In this paper we give an approximate answer to a question of Nash-Williams from 1970: we show that for every $\alpha > 0$, every sufficiently large graph on $n$ vertices with minimum degree at least $(1/2 + \alpha)n$ contains at least $n/8$ edge-disjoint Hamilton cycles. More generally, we give an asymptotically best possible answer for the number of edge-disjoint Hamilton cycles that a graph $G$ with minimum degree $\delta$ must have. We also prove an approximate version of another long-standing conjecture of Nash-Williams: we show that for every $\alpha > 0$, every (almost) regular and sufficiently large graph on $n$ vertices with minimum degree at least $(1/2 + \alpha)n$ can be almost decomposed into edge-disjoint Hamilton cycles.

1. Introduction

Dirac’s theorem [2] states that every graph on $n \geq 3$ vertices of minimum degree at least $n/2$ contains a Hamilton cycle. The theorem is best possible since there are graphs of minimum degree at least $\lfloor (n-1)/2 \rfloor$ which do not contain any Hamilton cycle.

Nash-Williams [13] proved the surprising result that the conditions of Dirac’s theorem, despite being best possible, even guarantee the existence of many edge-disjoint Hamilton cycles.

**Theorem 1** ([13]). Every graph on $n$ vertices of minimum degree at least $n/2$ contains at least $\lfloor 5n/224 \rfloor$ edge-disjoint Hamilton cycles.

Nash-Williams [12, 13, 14] asked whether the above bound on the number of Hamilton cycles can be improved. Clearly we cannot expect more than $\lfloor (n+1)/4 \rfloor$ edge-disjoint Hamilton cycles and Nash-Williams [12] initially conjectured that one might be able to achieve this. However, soon afterwards, it was pointed out by Babai (see [12]) that this conjecture is false. Babai’s idea was carried further by Nash-Williams [12] who gave an example of a graph on $n = 4m$ vertices with minimum degree $2m$ having at most $\lfloor (n+4)/8 \rfloor$ edge-disjoint Hamilton cycles. Here is a similar example having at most $\lfloor (n+2)/8 \rfloor$ edge-disjoint Hamilton cycles: Let $A$ be an empty graph on $2m$ vertices, $B$ a graph consisting of $m+1$ disjoint edges and let $G$ be the graph obtained from the disjoint union of $A$ and $B$ by adding all possible edges between $A$ and $B$. So $G$ is a graph on $4m+2$ vertices with minimum degree $2m+1$. Observe that any Hamilton cycle of $G$ must use at least 2 edges from $B$ and thus $G$ has at most $\lfloor (m+1)/2 \rfloor$ edge-disjoint Hamilton cycles. We will prove that this example is asymptotically best possible.

**Theorem 2.** For every $\alpha > 0$ there is an integer $n_0$ so that every graph on $n \geq n_0$ vertices of minimum degree at least $(1/2 + \alpha)n$ contains at least $n/8$ edge-disjoint Hamilton cycles.
Nash-Williams [12, 14] pointed out that the construction described above depends heavily on the graph being non-regular. He thus conjectured [14] the following, which if true is clearly best possible.

**Conjecture 3 ([14]).** Let \( G \) be a \( d \)-regular graph on at most \( 2d \) vertices. Then \( G \) contains \( \lfloor d/2 \rfloor \) edge-disjoint Hamilton cycles.

The conjecture was also raised independently by Jackson [5]. For complete graphs, its truth follows from a construction of Walecki (see e.g. [1, 10]). The best result towards this conjecture is the following result of Jackson [5].

**Theorem 4 ([5]).** Let \( G \) be a \( d \)-regular graph on \( 14 \leq n \leq 2d + 1 \) vertices. Then \( G \) contains \( \lfloor (3d - n + 1)/6 \rfloor \) edge-disjoint Hamilton cycles.

In this paper we prove an approximate version of Conjecture 3.

**Theorem 5.** For every \( \alpha > 0 \) there is an integer \( n_0 \) so that every \( d \)-regular graph on \( n \geq n_0 \) vertices with \( d \geq (1/2 + \alpha)n \) contains at least \( (d - \alpha n)/2 \) edge-disjoint Hamilton cycles.

In fact, we will prove the following more general result which states that Theorem 5 is true for almost regular graphs as well. Note that the construction showing that one cannot achieve more than \( \lfloor (n + 2)/8 \rfloor \) edge-disjoint Hamilton cycles under the conditions of Dirac’s theorem is almost regular. However in the following result we also demand that the minimum degree is a little larger than \( n/2 \).

**Theorem 6.** There exists \( \alpha_0 > 0 \) so that for every \( 0 < \alpha \leq \alpha_0 \) there is an integer \( n_0 \) for which every graph on \( n \geq n_0 \) vertices with minimum degree \( \delta \geq (1/2 + \alpha)n \) and maximum degree \( \Delta \leq \delta + \alpha^2 n/5 \) contains at least \( (\delta - \alpha n)/2 \) edge-disjoint Hamilton cycles.

Frieze and Krivelevich [3] proved that the above results hold if one also knows that the graph is quasi-random (in which case one can drop the condition on the minimum degree). So in particular, it follows that a binomial random graph \( G_{n,p} \) with constant edge probability \( p \) can ‘almost’ be decomposed into Hamilton cycles with high probability. For such \( p \), it is still an open question whether one can improve this to show that with high probability the number of edge-disjoint Hamilton cycles is exactly half the minimum degree – see e.g. [3] for a further discussion. Our proof makes use of the ideas in [3].

Finally, we answer the question of what happens if we have a better bound on the minimum degree than in Theorem 2. The following result approximately describes how the number of edge-disjoint Hamilton cycles guaranteed in \( G \) gradually approaches \( \delta(G)/2 \) as \( \delta(G) \) approaches \( n - 1 \).

**Theorem 7.**

(i) For all positive integers \( \delta, n \) with \( n/2 < \delta < n \), there is a graph \( G \) on \( n \) vertices with minimum degree \( \delta \) such that \( G \) contains at most

\[
\frac{\delta + 2 + \sqrt{n(2\delta - n)}}{4}
\]

edge-disjoint Hamilton cycles.

(ii) For every \( \alpha > 0 \), there is a positive integer \( n_0 \) so that every graph on \( n \geq n_0 \) vertices of minimum degree \( \delta \geq (1/2 + \alpha)n \) contains at least

\[
\frac{\delta - \alpha n + \sqrt{n(2\delta - n)}}{4}
\]

edge-disjoint Hamilton cycles.
Observe that Theorem 2 is an immediate consequence of Theorem 7(ii). In Section 2 we will give a simple construction which proves Theorem 7(i). This construction also yields an analogue of Theorem 7 for $r$-factors, where $r$ is even: Clearly, Theorem 7(ii) implies the existence of an $r$-factor for any even $r$ which is at most twice the bound in (1). The construction in Section 2 shows that this is essentially best possible. The question of which conditions on a graph guarantee an $r$-factor has a huge literature, see the survey by Plummer for a recent overview [15].

It turns out that the proofs of Theorems 6 and 7(ii) are very similar and we will thus prove these results simultaneously. In Section 3 we give an overview of the proof. In Section 4 we introduce some notation and also some tools that we will need in the proofs of Theorems 6 and 7(ii). We prove these theorems in Section 5.

Another long-standing conjecture in the area is due to Kelly (see e.g. [11]). It states that any regular tournament can be decomposed into edge-disjoint Hamilton cycles. Very recently, an approximate version of this conjecture was proved in [8]. The basic proof strategy is common to both papers. So we hope that the proof techniques will also be useful for further decomposition problems.

2. PROOF OF THEOREM 7(i)

If $\delta = n - 1$, then $K_n$ contains at most

$$\frac{n - 1}{2} = \frac{n + (n - 2)}{4} < \frac{n + 1 + \sqrt{n(n - 2)}}{4} = \frac{\delta + 2 + \sqrt{n(2\delta - n)}}{4}$$

equal-disjoint Hamilton cycles. So from now on we will assume that $\delta \leq n - 2$.

The construction of the graph $G$ is very similar to the construction in the introduction showing that we might not have more than $\lceil (n+2)/8 \rceil$ edge-disjoint Hamilton cycles. Here, $G$ will be the disjoint union of an empty graph $A$ of size $n - \Delta$, and a $(\delta + \Delta - n)$-regular graph $B$ on $\Delta$ vertices, together with all edges between $A$ and $B$ (see Figure 1). Such a graph $B$ exists if for example $\Delta$ is even (see e.g. [9, Problem 5.2]).

![Figure 1. A graph $G$ on $n$ vertices with minimum degree at least $\delta > n/2$ having at most $\frac{\delta + 2 + \sqrt{n(2\delta - n)}}{2}$ edge-disjoint Hamilton cycles.](image)

The value of $\Delta$ will be chosen later. At the moment we will only demand that $\Delta$ is an even integer satisfying $\delta \leq \Delta \leq n - 1$. Observe that $G$ is a graph on $n$ vertices with minimum degree $\delta$ and maximum degree $\Delta$. We claim that $G$ cannot contain more than $\frac{\Delta(\delta + \Delta - n)}{2(2\Delta - n)}$ edge-disjoint Hamilton cycles. In fact, we claim that it can only contain an $r$-factor if $r \leq \frac{\Delta(\delta + \Delta - n)}{2\Delta - n}$. Indeed, given any $r$-factor $H$ of $G$, since $e_H(A, B) = \sum_{v \in A} d_H(v) =$
r(n - Δ), we deduce that
\[ rΔ = \sum_{v \in B} d_H(v) \leq Δ(δ + Δ - n) + r(n - Δ) \]
from which our claim follows. It remains to make a judicious choice for Δ and to show that it implies the result. One can check that \( \frac{n + \sqrt{n(2δ - n)}}{2} \) minimizes \( f(x) = x(δ + x - n)/(2x - n) \) in \([δ, n]\). (This is only used as a heuristic and it is not needed in our argument.) It can be also checked that since \( δ \leq n - 2 \) we have \( δ \leq \frac{n + \sqrt{n(2δ - n)}}{2} < n - 1 \). Indeed, the first inequality holds if and only if \( (2δ - n)^2 \leq n(2δ - n) \) which is true as \( n/2 \leq δ \leq n \) and the second inequality holds since
\[ \frac{n + \sqrt{n(2δ - n)}}{2} \leq \frac{n + \sqrt{n^2 - 4n}}{2} < \frac{n + (n - 2)}{2} = n - 1. \]
We define \( Δ = \frac{n + \sqrt{n(2δ - n)}}{2} + ε \), where \( ε \) is chosen so that \( |ε| \leq 1 \) and \( Δ \) is an even integer satisfying \( δ \leq Δ \leq n - 1 \). We claim that this value of \( Δ \) gives the desired bound. To see this, recall that if \( G \) contains an \( r \)-factor, then we must have
\[ r \leq \frac{Δ(δ + Δ - n)}{2Δ - n} = \frac{δ}{2} + \frac{nδ/2}{2Δ - n} - \frac{Δ(n - Δ)}{2Δ - n} \]
and that
\[ Δ(n - Δ) = \left( \frac{n}{2} + \left( \frac{\sqrt{n(2δ - n)}}{2} + ε \right) \right) \left( \frac{n}{2} - \left( \frac{\sqrt{n(2δ - n)}}{2} + ε \right) \right) \]
\[ = \frac{n^2}{4} - \frac{n(2δ - n)}{4} - ε\sqrt{n(2δ - n)} - ε^2 = \frac{n^2 - nδ}{4} - ε\sqrt{n(2δ - n)} - ε^2. \]
Thus
\[ r \leq \frac{δ}{2} + \frac{n(2δ - n) + 2ε\sqrt{n(2δ - n)}}{2(2Δ - n)} + \frac{ε^2}{2Δ - n}. \]
Since also \( (2Δ - n)\sqrt{n(2δ - n)} = n(2δ - n) + 2ε\sqrt{n(2δ - n)} \), we deduce that
\[ r \leq \frac{δ + \sqrt{n(2δ - n)}}{2} + \frac{ε^2}{2Δ - n} \leq \frac{δ + 2 + \sqrt{n(2δ - n)}}{2}, \]
as required.

### 3. Proof overview of the main theorems

In the overview we will only discuss the case in which \( G \) is regular, say of degree \( λn \) with \( λ > 1/2 \). The other cases are similar and in fact will be treated simultaneously in the proof itself. We begin by defining additional constants such that
\[ 0 < ε \ll β \ll γ \ll 1. \]

By applying the Regularity Lemma to \( G \), we obtain a partition of \( G \) into clusters \( V_1, \ldots, V_k \) and an exceptional set \( V_0 \). Moreover, most pairs of clusters span an \( ε \)-regular (i.e. quasi-random) bipartite graph. It turns out that for our purposes the ‘standard’ reduced graph defined on the clusters does not capture enough information about the original graph \( G \). So we will instead work with the multigraph \( R \) on vertex set \( \{V_1, \ldots, V_k\} \) in which there are exactly \( \ell_{ij} := |d(V_i, V_j)/β| \) multiple edges between the vertices \( V_i \) and \( V_j \) of \( R \) (provided that the pair \( (V_i, V_j) \) is \( ε \)-regular). Here \( d(V_i, V_j) \) denotes the density of the bipartite subgraph induced by \( V_i \) and \( V_j \). Then \( R \) is almost regular, with all degrees close to \( λk/β \). In particular, we can use Tutte’s \( f \)-factor theorem (see Theorem 12(ii)) to deduce that \( R \) contains an \( r \)-regular submultigraph \( R' \) where \( r \) is still close to \( λk/β \). By Petersen’s
the bipartite graphs which form vertices of all their neighbours on all vertices of C. We can then use this to find a cycle C' containing precisely all vertices of P. In the final step, we make use (amongst others) of the quasi-randomness of the bipartite graphs which form H_{3,i}. 

We now partition (most of) the edges of G in such a way that each matching edge is assigned roughly the same number of edges of G. More precisely, given two adjacent clusters U, V of R, the edge set E_G(U, V) can be decomposed into ℓ_{ij} bipartite graphs so that each is ε-regular with density close to β. These ℓ_{ij} regular pairs correspond to the ℓ_{ij} edges in R between U and V. Thus, for each matching M_i, we can define a subgraph G_i of G such that all G_i’s are edge-disjoint and they consist of a union of k' := k/2 pairs of clusters which are ε-regular of density about β, together with the exceptional set V_0. Let m denote the size of a cluster. By moving some additional vertices to the exceptional set, we may assume that for every such pair of clusters of G_i, all vertices have degree close to βm. So for each i, we now have a set V_0_i consisting of the exceptional set V_0 together with the vertices moved in the previous step. For each G_i we will aim to find close to βm/2 edge-disjoint Hamilton cycles consisting mostly of edges of G_i and a few further edges which do not belong to any of the G_i.

Because G may not have many edges which do not belong to any of the G_i, (in fact it may have none) before proceeding we extract random subsets of edges from each G_i to get disjoint subgraphs H_1, H_2 and H_3 of G each of density about γ which satisfy several other useful properties as well. Moreover, each pair of clusters of G_i corresponding to an edge of M_i will still be super-regular of density almost β. Each of the subgraphs H_1, H_2 and H_3 will be used for a different purpose in the proof.

H_1 will be used to connect the vertices of each V_0_i to G_i \ V_0_i so that the vertices of V_0_i have almost βm neighbours in V(G_i) \ V_0_i. Moreover the edges added to G_i will be well spread-out in the sense that no vertex of G_i \ V_0_i will have large degree in V_0_i. So every vertex of G_i now has degree close to βm.

Next, our aim is to find an s-regular spanning subgraph S_i of G_i with s close to βm. In order to achieve this, it turns out that we will first need to add some edges to G_i between pairs of clusters which do not correspond to edges of M_i. We will take these from H_2.

We may assume that the degree of S_i is even and thus by Petersen’s theorem it can be decomposed into 2-factors. It will remain to use the edges of H_3 to transform each of these 2-factors into a Hamilton cycle. Several problems may arise here. Most notably, the number of edges of H_3 will need in order to transform a given 2-factor F into a Hamilton cycle will be proportional to the number of cycles of F. So if we have a linear number of 2-factors F which have a linear number of cycles, then we will need to use a quadratic number of edges from H_3 which would destroy most of its useful properties. However, a result from [3] based on estimating the permanent of a matrix implies that the average number of cycles in a 2-factor of S_i is o(n). We will apply a variant of this result proved in [7, 8]. So we can assume that our 2-factors have o(n) cycles.

To complete the proof we will consider a random partition of the graph H_3 into subgraphs H_{3,1}, ..., H_{3,r}, one for each graph G_i. We will use the edges of H_{3,i} to transform all 2-factors of S_i into Hamilton cycles. We will achieve this by considering each 2-factor F successively. For each F, we will use the rotation-extension technique to successively merge its cycles. Roughly speaking, this means that we obtain a path P with endpoints x and y (say) by removing a suitable edge of a cycle of F. If F is not a Hamilton cycle and H_{3,i} has an edge from x or y to another cycle C of F, and we can extend P to a path containing all vertices of C as well. We continue in this way until in H_{3,i} both endpoints of P have all their neighbours on P. We can then use this to find a cycle C' containing precisely all vertices of P. In the final step, we make use (amongst others) of the quasi-randomness of the bipartite graphs which form H_{3,i}. 

4. Notation and Tools

4.1. Notation. Given vertex sets $A$ and $B$ in a graph $G$, we write $E_G(A, B)$ for the set of all edges $ab$ with $a \in A$ and $b \in B$ and put $e_G(A, B) = |E_G(A, B)|$. We write $(A, B)_G$ for the bipartite subgraph of $G$ whose vertex classes are $A$ and $B$ and whose set of edges is $E_G(A, B)$. We drop the subscripts if this is unambiguous. Given a set $E' \subseteq E_G(A, B)$, we also write $(A, B)_{E'}$ for the bipartite subgraph of $G$ whose vertex classes are $A$ and $B$ and whose set of edges is $E'$. Given a vertex $x$ of $G$ and a set $A \subseteq V(G)$, we write $d_A(x)$ for the number of neighbours of $x$ in $A$.

To prove Theorems 6 and 7(ii) it will be convenient to work with multigraphs instead of just (simple) graphs. All multigraphs considered in this paper will be without loops.

We sometimes write $a = b \pm c$ to mean that the real numbers $a, b, c$ satisfy $|a - b| \leq c$. To avoid unnecessarily complicated calculations we will sometimes omit floor and ceiling signs and treat large numbers as if they were integers. We will also sometimes treat large numbers as if they were even integers.

4.2. Chernoff Bounds. Recall that a Bernoulli random variable with parameter $p$ takes the value 1 with probability $p$ and the value 0 with probability $1 - p$. We will use the following Chernoff-type bound for a sum of independent Bernoulli random variables.

**Theorem 8** (Chernoff Inequality). Let $X_1, \ldots, X_n$ be independent Bernoulli random variables with parameters $p_1, \ldots, p_n$ respectively and let $X = X_1 + \cdots + X_n$. Then

$$
\Pr(|X - EX| \geq t) \leq 2 \exp\left(-\frac{t^2}{3EX}\right).
$$

In particular, since a binomial random variable $X$ with parameters $n$ and $p$ is a sum of $n$ independent Bernoulli random variables, the above inequality holds for binomial random variables as well.

4.3. Regularity Lemma. In the proof, we will use the degree form of Szemerédi’s Regularity Lemma. Before stating it, we need to introduce some notation. The density of a bipartite graph $G = (A, B)$ with vertex classes $A$ and $B$ is defined to be $d_G(A, B) := \frac{e(A, B)}{|A||B|}$. We sometimes write $d(A, B)$ for $d_G(A, B)$ if this is unambiguous. Given $\varepsilon > 0$, we say that $G$ is $\varepsilon$-regular if for all subsets $X \subseteq A$ and $Y \subseteq B$ with $|X| \geq \varepsilon|A|$ and $|Y| \geq \varepsilon|B|$ we have that $|d(X, Y) - d(A, B)| < \varepsilon$. Given $d \in [0, 1]$, we say that $G$ is $(\varepsilon, d)$-super-regular if it is $\varepsilon$-regular and furthermore $d_G(a) \geq d|B|$ for all $a \in A$ and $d_G(b) \geq d|A|$ for all $b \in B$. We will use the following degree form of Szemerédi’s Regularity Lemma:

**Lemma 9** (Regularity Lemma; Degree form). For every $\varepsilon \in (0, 1)$ and each positive integer $M'$, there are positive integers $M$ and $n_0$ such that if $G$ is any graph on $n \geq n_0$ vertices and $d \in [0, 1]$ is any real number, then there is a partition of the vertices of $G$ into $k + 1$ classes $V_0, V_1, \ldots, V_k$, and a spanning subgraph $G'$ of $G$ with the following properties:

- $M' \leq k \leq M$;
- $|V_0| \leq \varepsilon n, |V_1| = \cdots = |V_k| =: m$;
- $d_G(v) \geq d_G(v) - (d + \varepsilon)n$ for every $v \in V(G)$;
- $G'[V_i]$ is empty for every $0 \leq i \leq k$;
- all pairs $(V_i, V_j)$ with $1 \leq i < j \leq k$ are $\varepsilon$-regular with density either 0 or at least $d$.

We call $V_1, \ldots, V_k$ the clusters of the partition and $V_0$ the exceptional set.

4.4. Factor Theorems. An $r$-factor of a multigraph $G$ is an $r$-regular submultigraph $H$ of $G$. We will use the following classical result of Petersen.

**Theorem 10** (Petersen’s Theorem). Every regular multigraph of positive even degree contains a 2-factor.
Furthermore, we will use Tutte’s f-factor theorem [16] which gives a necessary and sufficient condition for a multigraph to contain an f-factor. (In fact, the theorem is more general.) Before stating it we need to introduce some notation. Given a multigraph $G$, a positive integer $r$, and disjoint subsets $T, U$ of $V(G)$, we say that a component $C$ of $G[U]$ is odd (with respect to $r$ and $T$) if $e(C, T) + r|C|$ is odd. We write $q(U)$ for the number of odd components of $U$.

**Theorem 11.** A multigraph $G$ contains an $r$-factor if and only if for every partition of the vertex set of $G$ into sets $S, T, U$, we have

$$\sum_{v \in T} d(v) - e(S, T) + r(|S| - |T|) \geq q(U). \quad (2)$$

In fact, we will only need the following consequence of Theorem 11.

**Theorem 12.** Let $G$ be a multigraph on $n$ vertices of minimum degree $\delta \geq \ell n/2$, in which every pair of vertices is joined by at most $\ell$ edges.

(i) Let $r$ be an even number such that $r \leq \frac{\delta - \ell \sqrt{\ell n(2\delta - \ell n)}}{2}$. Then $G$ contains an $r$-factor.

(ii) Let $0 < \xi < 1/9$ and suppose $(1/2 + \xi)\ell n \leq \Delta(G) \leq \delta + \xi \ell n$. If $r$ is an even number such that $r \leq \delta - \xi \ell n$ and $n$ is sufficiently large, then $G$ contains an $r$-factor.

The case when $\ell = 1$ and $r$ is close to $n/4$ in (i) was already proven by Katerinis [6].

**Proof.** By Theorem 10, in both (i) and (ii) it suffices to consider the case that $r$ is the maximal positive even integer satisfying the conditions. Observe that since $\delta \leq \ell(n - 1) < \ell n$ it follows that $\ell n(\delta - \ell n) = \delta^2 - (\ell n - \delta)^2 < \delta^2$, so in case (i) we have $r < \delta$ and since both $r$ and $\delta$ are integers we have $r \leq \delta - 1$. This also holds in case (ii).

By Theorem 11, it is enough to show (in both cases) that (2) holds for every partition of the vertex set of $G$ into sets $S, T$ and $U$.

**Case 1.** $\ell |T| \leq r - 1$ and $\ell |S| \leq \delta - r$.

Since in this case $d_T(v) \leq 2|T| \leq \ell n$ for every $v \in V(G)$, the left hand side of (2) is

$$\sum_{v \in T} (d(v) - r) + \sum_{v \in S} (r - d_T(v)) \geq |T| + |S|.$$ 

So in this case, it is enough to show that $q(U) \leq |T| + |S|$. If $|T| = 0$, the result holds since in this case no component of $G[U]$ is odd, i.e $q(U) = 0$. If $|T| = 1$ and $|S| = 0$, then the degree conditions imply that $G[U]$ is connected and so $q(U) \leq 1 = |T| + |S|$. (Indeed, the degree conditions imply that the undirected graph obtained from $G$ by ignoring multiple edges has minimum degree at least $n/2$ and so any subgraph of it on $n - 1$ vertices must be connected.) Thus in this case, we may assume that $2 \leq |T| + |S| \leq \frac{\delta - 1}{\ell}$. Observe that every vertex $v \in U$ has at most $\ell(|T| + |S|)$ neighbours in $T \cup S$ when counting multiplicity and so it has at least $\frac{\delta - \ell(|T| + |S|)}{\ell}$ distinct neighbours in $U$. In particular, every component of $G[U]$ contains at least $\frac{\delta - \ell(|T| + |S|)}{\ell}$ vertices and so certainly $q(U) \leq \frac{\ell |U|}{\delta - \ell(|T| + |S|)}$. Writing $k := |T| + |S|$, it is enough in this case to prove that $k \geq \frac{\ell(n - k)}{\delta - \ell k}$. But this is equivalent to proving that $k \delta + 2k\ell - \ell k^2 - \ell n \geq 0$, which is true since the left hand side is equal to $(k - 2)(\delta - \ell k) + 2\delta - \ell n$.

**Case 2.** $\ell |T| = r$.

Since for every vertex $v \in S$ we have $d_T(v) \leq \ell |T| = r$, it follows that $r|S| \geq e(S, T)$. Thus the left hand side of (2) is at least $(\delta - r)|T| = (\delta - r)r/\ell$. Observe that $G[U]$ has at most $n - \delta/\ell$ components. Indeed, if $C$ is a component of $G[U]$ and $x$ is a vertex of $C$, then as $x$ can only have neighbours in $C \cup S \cup T$ we have that $|C \cup S \cup T| \geq 1 + \delta/\ell$ and so $U$ has at most $n - 1 - \delta/\ell$ other components. Thus, it is enough to show that
For case (ii) (recall that \( r \) is maximal subject to the given conditions) we have \((\delta - r)r \geq \xi ln(\delta - \xi ln - 2) \geq \ell n - \delta\). To see the last inequality, recall that \(\delta \geq \ell n / 2\) and \(\xi ln \geq 4\) say (as we assume that \( n \) is sufficiently large). So \(\xi ln(\delta - \xi ln - 2) \geq 4(\ell n(1/2 - \xi) - 2) = (2-4\xi)\ell n - 8 \geq \ell n\). To prove (i), note that we (always) have

\[
(\delta - r)r = \frac{\delta^2}{4} - \left(\frac{r - \delta}{2}\right)^2 \geq \frac{\delta^2}{4} - \frac{\ell n(2\delta - \ell n)}{4} = \left(\frac{\ell n - \delta}{2}\right)^2. 
\]

So the left hand side of (2) is at least \((\delta - r)r \geq \ell n - \delta\). To prove (ii) we may assume that \(\delta \leq \ell n\) unless \(\delta \geq \ell n - 3\). But if this is the case, then \((\delta - r)r \geq \ell n - \delta\) unless \(\delta = 2, \delta = 3\) and \(\ell n = 6\). But this violates the assumption on \( r \) in (i).

**Case 3.** \(|T| \geq \frac{\ell n + 1}{\ell} - \frac{\delta - r + 1}{\ell}\).

Since \(q(U) \leq |U| = n - |S| - |T|\), it is enough to show that in this case we have

\[
(\delta - r + 1)|T| + (r + 1)|S| - \ell |S||T| \geq n.
\]

By writing the left hand side of (4) as

\[
\frac{(\delta - r + 1)(r + 1)}{\ell} - \ell \left(\frac{|T| - r + 1}{\ell}\right)\left(\frac{|S| - \delta - r + 1}{\ell}\right),
\]

we observe that it is minimized when \(|T| + |S|\) is maximal, i.e. it is equal to \( n \). To prove (i), observe that the left hand side of (4) is at least

\[
\frac{(\delta - r + 1)(r + 1)}{\ell} - \ell \left(\frac{n - \delta + 2}{\ell}\right)^2 = \frac{(\delta - r)r}{\ell} + \frac{\delta + 1}{\ell} - \frac{\ell n^2}{4} + \frac{n(\delta - 2)}{2} - \frac{(\delta + 2)^2}{4\ell}.
\]

\[
\geq \frac{(\ell n - \delta)^2}{4\ell} + \frac{\delta + 1}{\ell} - \frac{\ell n^2}{4} + \frac{n(\delta + 2)}{2} - \frac{(\delta + 2)^2}{4\ell} = n.
\]

To prove (ii) we may assume that \(\delta < (1 - \sqrt{\xi})\ell n\). Indeed if \(\delta \geq (1 - \sqrt{\xi})\ell n\), then using that \( r \) is maximal subject to the given conditions we have

\[
(\delta - r)r \geq \xi ln(\delta - \xi ln - 2) \geq \xi ln \left(\frac{1}{2} - \xi\right) ln - 2 \geq \xi ln^2 \geq \frac{(\ell n - \delta)^2}{4}
\]

and the result follows exactly as in case (i).

If also \(|T| \leq \frac{\Delta}{\ell}\), then we claim that \(|T| - \frac{\ell n + 1}{\ell} \leq |S| - \frac{\delta - r + 1}{\ell}\). Indeed, this follows since

\[
|T| - |S| \leq \frac{2\Delta}{\ell} - n \leq \frac{2\delta}{\ell} + 2\xi n - \frac{2\xi^2 n}{\ell} - \frac{\delta}{\ell} + 2\xi^2 n - \sqrt{\xi} n \leq \frac{2r - \delta}{\ell} + 2\xi n - \sqrt{\xi} n = \frac{2r - \delta}{\ell} + (2\xi^2 + 2\xi - \sqrt{\xi}) n + \frac{4}{\ell} \leq \frac{2r - \delta}{\ell}.
\]

This claim together with the fact that \(|T| + |S| = n\) implies that (5) (and thus the left hand side of (4)) is minimized when \(|T| = \Delta / \ell\) and \(|S| = n - \Delta / \ell\). Note that \(|T| \geq (1/2 + \xi)n\) in this case and so \(|T| - |S| \geq 2\xi n\). Thus the left hand side of (4) is at least

\[
(\delta - r)|T| + (r - \ell |T|)|S| = (\delta - r)(|T| - |S|) + (\delta - \Delta)|S| \geq 2\xi^2 \ell n^2 - 2\xi^2 \ell n^2 \geq n.
\]

To complete the proof, suppose \(|T| \geq \frac{\Delta}{\ell} + \frac{1}{\ell} |S| \geq \frac{\delta - r + 1}{\ell} \) but not both.

**Case 4.** \(|T| \geq \frac{\ell n + 1}{\ell} \) or \(|S| \geq \frac{\delta - r + 1}{\ell} \).
As in Case 3 it suffices to show that (4) holds. (5) shows that in this case the left hand side of (4) is at least \((\delta - r + 1)(r + 1)/\ell\). So (i) holds since (6) implies that the left hand side of (4) is at least \(n\). For (ii), note that
\[
\frac{(\delta - r + 1)(r + 1)}{\ell} \geq \frac{\xi \ell n (r + 1)}{\ell} \geq \xi n (\delta - \xi \ell n - 1) \geq n.
\]
(Here we use the maximality of \(r\) in both inequalities.)

5. Proofs of the Main Theorems

In this section we will prove Theorems 6 and 7(ii) simultaneously. Observe that in both cases we may assume that \(\alpha \ll 1\). Define additional constants such that
\[
\frac{1}{n_0} \ll \zeta \ll 1/M' \ll \varepsilon \ll \beta \ll n_0 \ll \gamma \ll \alpha
\]
and let \(G\) be a graph on \(n \geq n_0\) vertices with minimum degree \(\delta \geq (1/2 + \alpha)n\) and maximum degree \(\Delta\).

5.1. Applying the Regularity Lemma. We apply the Regularity Lemma to \(G\) with parameters \(\varepsilon/2, 3d/2\) and \(M'\) to obtain a partition of \(G\) into clusters \(V_1, \ldots, V_k\) and an exceptional set \(V_0\), and a spanning subgraph \(G'\) of \(G\). Let \(R\) be the multigraph on vertex set \(\{V_1, \ldots, V_k\}\) obtained by adding exactly \(\ell_{ij} := |d_{G'}(V_i, V_j)/\beta|\) multiple edges between the vertices \(V_i\) and \(V_j\) of \(R\). By removing one vertex from each cluster if necessary and adding all these vertices to \(V_0\), we may assume that \(m := |V_1| = \cdots = |V_k|\) is even. So now \(|V_0| \leq \varepsilon n/2 + k \leq \varepsilon n\). The next lemma shows that \(R\) inherits its minimum and maximum degree from \(G\).

Lemma 13.
\begin{itemize}
\item[(i)] \(\delta(R) \geq \left(\frac{\delta}{2} - 2d\right)\frac{k}{\beta}\); \(\Delta(R) \leq \left(\frac{\Delta}{2} + 2d\right)\frac{k}{\beta}\).
\end{itemize}

Proof. For any cluster \(V_i\) of \(R\) we have
\[
\sum_{x \in V_i} d_{G'}(x) \leq e(V_0, V_i) + \sum_{j \neq i} e_{G'}(V_i, V_j) \leq \varepsilon mn + \sum_{j \neq i} d_{G'}(V_i, V_j)m^2.
\]
Since \(d_{G'}(V_i, V_j) \leq \beta(\ell_{ij} + 1)\), we obtain
\[
\sum_{x \in V_i} d_{G'}(x) \leq \varepsilon mn + (d_R(V_i) + k)\beta m^2.
\]
By the definition of \(G'\) in the Regularity Lemma we also have
\[
\sum_{x \in V_i} d_R(x) \geq \sum_{x \in V_i} (d_G(x) - (3d/2 + \varepsilon)n) \geq \delta m - (3d/2 + \varepsilon)mn.
\]
Since also \(\varepsilon, \beta \ll d\), (i) follows. Similarly,
\[
d_R(V_i) \beta m^2 \leq \sum_{j \neq i} d_{G'}(V_i, V_j)m^2 \leq \sum_{x \in V_i} d_{G'}(x) \leq \Delta m,
\]
so (ii) follows. \(\square\)

Since \(\delta \geq (1/2 + \alpha)n\) and since between any two vertices of \(R\) there are at most \(1/\beta\) edges, Theorem 12(i) implies that \(R\) contains an \(r\)-regular submultigraph \(R'\) for every even positive integer \(r\) satisfying
\[
r \leq \left(\frac{\delta}{n} - 2d + \sqrt{\frac{2\delta}{n} - 4d - 1}\right) \frac{k}{2\beta} = \left(\delta - 2dn + \sqrt{2\delta n - 4dn^2 - n^2}\right) \frac{k}{2\beta n}.
\]
In particular, (using the inequality $\sqrt{x-y} \geq \sqrt{x} - \sqrt{y}$ for $x \geq y > 0$ and the fact that $\alpha \gg d$) we may assume that

$$r = \left( \delta + \sqrt{n(2\delta - n)} - \alpha n/2 \right) \frac{k}{2\beta n}. \tag{7}$$

Moreover, for the proof of Theorem 6, we have $\Delta(R) - \delta(R) \leq (\log n / n) + 4d) \frac{k}{n} \leq \alpha^2 k / 4\beta$. Therefore, by taking $\xi = \alpha/2$ in Theorem 12(ii) we may even assume that

$$r = (\delta - 2\alpha n/3) \frac{k}{\beta n}. \tag{8}$$

So from now on, $R'$ is an $r$-regular submultigraph of $R$, where $r$ is even and is given by (7) for the proof of Theorem 7(ii) and given by (8) for the proof of Theorem 6.

By Theorem 10, $R'$ can be decomposed into 2-factors. As mentioned in the overview, it will be more convenient to work with a matching decomposition rather than a 2-factor decomposition. If all the cycles in all the 2-factor-decompositions had even length then we could decompose them into matchings. Because this might not be the case, we will split each cluster corresponding to a vertex of $R$ into two clusters to obtain a new multigraph $R^*$. More specifically, for each $1 \leq i \leq k$, we split each cluster $V_i$ arbitrarily into two pieces $V_i^1$ and $V_i^2$ of size $m/2$. $R^*$ is defined to be the multigraph on vertex set $V_1^1, V_1^2, \ldots, V_k^1, V_k^2$ where the number of multiedges between $V_i^a$ and $V_j^b$ ($1 \leq i,j \leq k, 1 \leq a,b \leq 2$) is equal to the number of multiedges of $R$ between $V_i$ and $V_j$.

Recall that by Theorem 10, $R'$ can be decomposed into 2-factors. We claim that each cycle $v_1 \ldots v_t$ of each 2-factor gives rise to two edge-disjoint even cycles in $R^*$ each of length $2t$, which themselves give rise to a total of four matchings in $R^*$, each of size $t$. Indeed, denoting by $a_i$ and $b_i$ the clusters in $R^*$ corresponding to $v_i$, if $t$ is even, say $t = 2s$, then we can take the cycles $a_1a_2 \ldots a_{2s}b_1b_2 \ldots b_{2s}$ and $a_1b_2 \ldots a_{2s-1}b_{2s}b_1a_2 \ldots b_{2s-1}a_{2s}$. If $t$ is odd, say $t = 2s + 1$, then we can take the cycles $a_1b_2 \ldots a_{2s-1}b_{2s}a_{2s+1}b_1b_{2s+1}a_{2s} \ldots b_3a_2$ and $a_1a_{2s+1}a_{2s} \ldots a_2b_1b_2 \ldots b_{2s+1}$ (see Figure 2 for the cases $t = 4, 5$).

![Figure 2. Cycles in $R'$ and the corresponding cycles in $R^*$.

To simplify the notation we will now make the following relabelings: $R'$ has served its purpose in finding a set of edge-disjoint perfect matchings in $R^*$ and it will not be used any more, $R^*$ is relabelled to $R$ and the clusters $V_1^1, V_1^2, \ldots, V_k^1, V_k^2$ are relabelled to $V_1, \ldots, V_k$. We also relabel $k'$ back to $k$. Note that now each $V_i$ has size $m' = m/2$ but we relabel $m'$ back to $m$.

In particular we can now assume that we have a partition of the vertex set of $G$ into $k$ clusters $V_1, \ldots, V_k$ and an exceptional set $V_0$, and a spanning subgraph $G'$ of $G$ satisfying the following properties:

- $|V_0| \leq \varepsilon n$ and $|V_1| = \cdots = |V_k| =: m$;
of them contains almost \( \beta m / G \) of pairs of clusters of \( G \) vertices. Observe that every cluster has degree (1 ± \( \varepsilon \))-regular and that every vertex remaining in each cluster has degree (\( \beta / G \))-super-regular.) We denote by \( E_{ij} \) the pair, we may assume that the pair is 2 \( \varepsilon \)-regular.

Later on, we will use that in both cases we have

\[
k/5\beta \leq r \leq k/\beta \quad \text{and} \quad \delta \geq r\beta m + \alpha n/5.
\]

We let \( M_1, \ldots, M_r \) be \( r \) edge-disjoint perfect matchings of \( R \). We will define edge-disjoint subgraphs \( G_1, \ldots, G_r \) of \( G \) corresponding to the matchings \( M_1, \ldots, M_r \). Before doing that, for each \( 1 \leq i < j \leq k \) we will find \( \ell_{ij} \) disjoint subsets \( E_{ij}^{V_1}, \ldots, E_{ij}^{V_j} \) of \( E_{G'}(V_i, V_j) \) corresponding to the \( \ell_{ij} \) edges \( f_{ij}^{V_1}, \ldots, f_{ij}^{V_j} \) of \( R \) between \( V_i \) and \( V_j \). The next well known observation shows that we can choose the \( E_{ij}^{V_i} \) so that each \( (V_i, V_j)_{E_{ij}^{V_i}} \) forms a regular pair.

It is e.g. a special case of Lemma 10(i) in [8]. To prove it, one considers a random partition of the edges of \( G' \) between \( V_i \) and \( V_j \).

**Lemma 14.** For each \( 1 \leq i < j \leq k \), there are \( \ell_{ij} \) edge-disjoint subsets \( E_{ij}^{V_1}, \ldots, E_{ij}^{V_j} \) of \( E_{G'}(V_i, V_j) \) such that each \( (V_i, V_j)_{E_{ij}^{V_i}} \) is \( \varepsilon \)-regular of density either 0 or \( \beta \pm \varepsilon \).

Given a matching \( M_i \), we define the graph \( G_i \) on vertex set \( V(G) \) as follows: Initially, the edge set of \( G_i \) is the union of the sets \( E_{ab}^{V_0} \), taken over all edges \( f_{ob}^{V_0} \) of \( M_i \). So at the moment, \( G_i \) is a disjoint union of \( V_0 \) and \( k' := k/2 \) pairs which are \( \varepsilon \)-regular and have density \( \beta \pm \varepsilon \). For every such pair, by removing exactly \( 2\varepsilon m \) vertices from each cluster of the pair, we may assume that the pair is \( 2\varepsilon \)-regular and that every vertex remaining in each cluster has degree \( (\beta \pm 4\varepsilon)m \) within the pair. (In particular, it is \( (2\varepsilon, \beta - 4\varepsilon) \)-super-regular.) We denote by \( V_{0i} \) the union of \( V_0 \) together with the set of all these removed vertices. Observe that

\[
|V_{0i}| \leq \varepsilon n + 2\varepsilon mk \leq 3\varepsilon n.
\]

Finally, we remove all edges incident to vertices of \( V_{0i} \). We will denote the pairs of clusters of \( G_i \) corresponding to the edges of \( M_i \) by \( (U_{1,i}, V_{1,i}), \ldots, (U_{k',i}, V_{k',i}) \) and call them the pairs of clusters of \( G_i \). Observe that every cluster \( V \) of \( G_i \) is contained in a unique cluster of \( R \), which we will denote by \( V^R \), and each cluster \( V \) of \( R \) contains a unique cluster of \( G_i \), which we will denote by \( V(i) \). In particular we have that \( |V \setminus V(i)| \leq 2\varepsilon m \).

So we have exactly \( r \) edge-disjoint spanning subgraphs \( G_i \) of \( G \) such that for each \( 1 \leq i \leq r \) the following hold:

1. Whenever \( G_i \) is a disjoint union of a set \( V_{0i} \) of size at most \( 3\varepsilon n \) together with \( k \) clusters \( U_{1,i}, V_{1,i}, \ldots, U_{k',i}, V_{k',i} \) each of size exactly \( (1 - 2\varepsilon)m \);
2. For each \( x \in V(G) \) the degree of \( x \) in \( G_i \) is either 0 if \( x \in V_{0i} \) or \( (\beta \pm 4\varepsilon)m \) otherwise;
3. Every edge of \( G_i \) lies in one of the pairs \( (U_{j,i}, V_{j,i}) \) for some \( 1 \leq j \leq k' \).

5.2. Extracting random subgraphs. At the moment, no \( G_i \) contains a Hamilton cycle. Our aim is to add some of the edges of \( G \) which do not belong to any of the \( G_i \) into the \( G_i \) in such a way that the graphs obtained from the \( G_i \) are still edge-disjoint and each of them contains almost \( \beta m / 2 \) edge-disjoint Hamilton cycles. To achieve this it will be
convenient however to remove some of the edges of each $G_i$ first while still keeping most of its properties.

We will show that there are edge-disjoint subgraphs $H_1, H_2$ and $H_3$ of $G$ satisfying the following properties:

**Lemma 15.** There are edge-disjoint subgraphs $H_1, H_2$ and $H_3$ of $G$ such that the following properties hold:

(i) For every vertex $x$ of $G$ and every $1 \leq j \leq 3$ we have $|d_{H_j}(x) - \gamma d_G(x)| \leq \zeta n$.

(ii) For every vertex $x$ of $G$, every $1 \leq i \leq r$ and every $1 \leq j \leq 3$

$$|d_{H_j \cap G_i}(x) - \gamma d_G_i(x)| \leq \zeta n.$$  

(iii) For every vertex $x$ of $G$, every $1 \leq i \leq r$ and every $1 \leq j \leq 3$

$$|\left|N_{H_j}(x) \cap V_0\right| - \gamma |N_G(x) \cap V_0| \right| \leq \zeta n.$$  

(iv) For every vertex $x$ of $G$, every $1 \leq i \leq r$, every $1 \leq t \leq k$ and every $1 \leq j \leq 3$

$$\left|\left|N_{H_j \cap G_i}(x) \cap V_t\right| - \gamma |N_G_i(x) \cap V_t| \right| \leq \zeta n.$$  

(v) For every vertex $x$ of $G$, every $1 \leq t \leq k$ and every $1 \leq j \leq 3$

$$\left|\left|N_{H_j}(x) \cap V_t\right| - \gamma |N_{G_i}(x) \cap V_t| \right| \leq \zeta n.$$  

(vi) For every $1 \leq i \leq r$, every pair of clusters $(U, V)$ of $G_i$, every $A \subseteq U$ and every $B \subseteq V$ with $|A|, |B| \geq 2\varepsilon |U|$ and every $1 \leq j \leq 3$ we have

$$\left|\left|E_{H_j \cap G_i}(A, B)\right| - \gamma |E_{G_i}(A, B)| \right| \leq \zeta n^2.$$  

(vii) For all clusters $U \neq V$ of $R$, every $A \subseteq U$ and every $B \subseteq V$ with $|A|, |B| \geq \varepsilon m$ and every $1 \leq j \leq 3$ we have

$$\left|\left|E_{H_j \cap G^r}(A, B)\right| - \gamma |E_{G^r}(A, B)| \right| \leq \zeta n^2.$$  

Proof. We construct the $H_j$’s randomly as follows: For every edge $e$ of $G$, with probability $3\gamma$, we assign it uniformly to one of the $H_j$’s and with probability $1 - 3\gamma$ to none of them. By Theorem 8, all properties hold with high probability. More specifically, the total probability of failure is at most

$$(6n + 6rn + 6rn + 6kn + 6kn) \exp \left( -\frac{\zeta^2 n}{3\gamma} \right) + (3rk4^m + 3k^24^m) \exp \left( -\frac{\zeta^2 n^2}{3\gamma} \right) \ll 1. \ \square$$

We pick subgraphs $H_1, H_2$ and $H_3$ of $G$ as given by Lemma 15. It will be convenient for later use to split (a subgraph of) $H_3$ into $r$ subgraphs called $H_{3,1}, \ldots, H_{3,r}$ satisfying the properties of the following lemma. For each $i$, we will add edges of $H_{3,i}$ to $G_i$ (but not to any of the other $G_j$) during the final part of our proof (see Section 5.8). Roughly speaking, if $(U, V)$ is an edge of $R$, then we require $H_{3,i}$ to contain some edges between $U$ and $V$ (but we do not need many of these edges). If $(U, V)$ corresponds to a matching edge of $M_i$, then we also require the corresponding subgraph of $H_{3,i}$ to be reasonably dense. Moreover, each edge of $H_{3,i}$ will correspond to some edge of $R$.

**Lemma 16.** There are edge-disjoint subgraphs $H_{3,1}, \ldots, H_{3,r}$ of $H_3$ so that the following hold:

(i) For every $1 \leq i \leq r$, all clusters $U \neq V$ of $G_i$ such that $U^R$ and $V^R$ are adjacent in $R$ and every $U' \subseteq U$ and $V' \subseteq V$ with $|U'|, |V'| \geq \varepsilon m$ there are at least $\frac{\gamma 2\varepsilon^2 d m^2}{3k}$ edges between $U'$ and $V'$ in $H_{3,i};$

(ii) For every $1 \leq i \leq r$ and every $1 \leq j \leq k'$, the pair $(U_{j,i}, V_{j,i})_{H_{3,i}}$ is $(5\varepsilon/2, \gamma \beta/5)$-super-regular;

(iii) For every $1 \leq i \leq r$, $H_{3,i}$ has maximum degree at most $\beta m;$. 

(iv) For every $1 \leq i \leq r$ and every edge $e$ of $H_{3,i}$ there are clusters $U \neq V$ of $G_i$ such that such that $U^R$ and $V^R$ are adjacent in $R$ and $e$ joins $U$ to $V$.

Proof. Recall that given any two adjacent vertices $V_a, V_b$ of $R$, and any $1 \leq \ell \leq \ell_{ab}$, there is at most one $M_i$ which contains the edge $f_{ab}^\ell$. If there is no such $M_i$, then we assign the edges of $E_{ab}^\ell \cap E(H_3)$ to the $H_{3,j}$ uniformly and independently at random. If there is such an $M_i$, we assign every edge of $E_{ab}^\ell \cap E(H_3)$ to $H_{3,i}$ with probability $1/2$ or to one of the other $H_{3,j}$’s uniformly at random. Note that this means that every edge of $H_3$ between $V_a$ and $V_b$ which lies in some $G_i$ is assigned to $H_{3,i}$ with probability $1/2$ and assigned to some other $H_{3,j}$ with probability $1/2(r - 1)$.

To prove (i), observe that since $r \leq k/\beta$ by (9), every edge of $H_3$ with endpoints in $U$ and $V$ has probability at least $\beta/2k$ of being assigned to $H_{3,i}$. Since $(U^R, V^R)_{G_i}$ is $\varepsilon$-regular of density at least $d$, there are at least $\varepsilon^2dm^2$ edges between $U'$ and $V'$ in $G'$ and so by Lemma 15(vii), $H_3$ contains at least $\gamma\varepsilon^2dm^2/2$ such edges. So by Theorem 8, (i) holds with high probability.

To prove (ii), recall that before defining $H_3$, the pair $(U_{j,i}, V_{j,i})_{G_i}$ was $(2\varepsilon, \beta - 4\varepsilon)$-super-regular by (a3). Thus by Lemma 15(iv) and (vi), $(U_{j,i}, V_{j,i})_{H_3 \cap G_i}$ is $(2\varepsilon, \gamma\beta/2)$-super-regular. Since every edge of $(U_{j,i}, V_{j,i})_{H_3 \cap G_i}$ has probability exactly $1/2$ of being assigned to $H_{3,i}$, another application of Theorem 8 shows that with high probability $(U_{j,i}, V_{j,i})_{H_3 \cap G_i}$ is $(2\varepsilon, \gamma\beta/5)$-super-regular. On the other hand, for every edge $e$ in $E(H_3) \setminus E(G_i)$ between $U_{j,i}$ and $V_{j,i}$, the probability that $e$ is assigned to $H_{3,i}$ is at most $1/r \leq 5\beta/k \ll \varepsilon$ (the first inequality follows from (9)). Together with Theorem 8 this implies that with high probability $(U_{j,i}, V_{j,i})_{H_3}$ consists of $(U_{j,i}, V_{j,i})_{H_3 \cap G_i}$ and at most $\varepsilon^3n^2$ additional edges. Thus with high probability $(U_{j,i}, V_{j,i})_{H_3}$ is $(5\varepsilon/2, \gamma\beta/5)$-super-regular, i.e. (ii) holds with high probability.

To prove (iii), observe that by (a2) and Lemma 15(ii) $(U_{j,i}, V_{j,i})_{H_3 \cap G_i}$ (and thus also $H_{3,i} \cap G_i$) has maximum degree at most $2\gamma\beta m$. Moreover, every edge in $E(H_3) \setminus E(G_i)$ has probability at most $1/r \leq 5\beta/k$ of being assigned to $H_{3,i}$. Since by Lemma 15(i) $H_3$ has maximum degree at most $2\gamma n$, this implies that $H_{3,i} \setminus E(G_i)$ has maximum degree at most $10\gamma\beta n/k$. Thus (iii) follows from Theorem 8 with room to spare.

In order to satisfy (iv) we delete all the edges of $H_{3,i}$ which do not ‘correspond’ to an edge of $R$.

We choose $H_{3,1}, \ldots, H_{3,r}$ as in Lemma 16. We now redefine each $G_i$ by removing from it every edge which belongs to one of the $H_j$’s. Observe that each $G_i$ still satisfies (a1) and (a4) and it also satisfies

(a2) For each $x \in V(G)$ the degree of $x$ in $G_i$ is either 0 if $x \in V_{0i}$ or $\beta(1 \pm 4\gamma)m$ otherwise;

(a3) For each $1 \leq j \leq k'$ the pair $(U_{j,i}, V_{j,i})$ is $(2\varepsilon, \beta(1 - 4\gamma))$-super-regular, instead of (a2) and (a3) respectively. Indeed, (a2) follows from (a2) and Lemma 15(ii) while (a3) follows from (a3) and Lemma 15(iv),(vi). Moreover, since we have removed the edges of $H_1, H_2$ and $H_3$ from the $G_i$’s we have

(a5) $G_1, \ldots, G_r, H_1, H_2, H_3$ are edge-disjoint.

5.3. Adding edges between $V_{0i}$ and $G_i \setminus V_{0i}$. Our aim in this subsection is to add edges from $G \setminus (G_1 \cup \cdots \cup G_r \cup H_2 \cup H_3)$ into the $G_i$’s so that for each $1 \leq i \leq r$ we have the following new properties:

(a2.1) For each $x \in V(G)$, we have $d_{G_i}(x) = (1 \pm 5\gamma)\beta m$;

(a2.2) For each $x \in G_i \setminus V_{0i}$, we have $d_{V_{0i}}(x) \leq \sqrt{2} \beta m$, instead of (a2). We will also guarantee that no edge will be added to more than one of the $G_i$’s. In particular, instead of (a5) we will now have
\((a'_4)\) \(G_1, \ldots, G_r, H_2, H_3\) are edge-disjoint.

Moreover, all edges added to \(G_i\) will have one endpoint in \(V_{0i}\) and the other endpoint in \(G_i \setminus V_{0i}\). In particular \((a_1)\) and \((a'_4)\) will still be satisfied while instead of \((a_4)\) we will have \((a'_4)\) Every edge of \(G_i\) lies either in a pair of the form \((V_{0i}, U)\) where \(U\) is a cluster of \(G_i\) (i.e. \(U = U_{i,j}\) or \(U = V_{i,j}\) for some \(1 \leq j \leq k\)) or in a pair of the form \((U_{j,i}, V_{j,i})\) for some \(1 \leq j \leq k'\).

We add the edges as follows: Firstly, for each vertex \(x\) of \(G\), we let \(L_x = \{i : x \in V_{0i}\}\). The distribution of the new edges incident to \(x\) will depend on the size of \(L_x\). Let us write \(\ell_x = |L_x|\) and let \(A = \{i : \ell_x \leq \gamma n/4 \beta m\}\) and \(B = V(G)\setminus A = \{i : \ell_x > \gamma n/4 \beta m\}\).

We begin by considering the edges of \(H_1\) incident to vertices of \(A\). For every such edge \(xy\), we choose one of its endpoints uniformly and independently at random. If the chosen endpoint, say \(x\), does not belong to \(A\), then we do nothing. If it does belong to \(A\) then we will assign \(xy\) to at most one of the \(G_i\)'s for which \(i \in L_x\). For each \(i \in L_x\), we assign \(xy\) to \(G_i\) with probability \(2 \beta m/d_{H_1}(x)\). So the probability that \(xy\) is not assigned to any \(G_i\) is \(1 - 2 \ell_x \beta m/d_{H_1}(x)\). (Moreover, this assignment is independent of any previous random choices.)

Observe that since \(\delta(G) \geq (1/2 + \alpha)n\), Lemma 15(i) implies that \(2 \ell_x \beta m/d_{H_1}(x) \leq \gamma n/4 \beta m \leq 1\), so this distribution is well defined. Finally, we remove all edges that lie within some \(V_{0i}\), so that each \(G_i[V_{0i}]\) becomes empty.

**Lemma 17.** With probability at least 2/3 the following properties hold:

(i) For every \(i\) and every \(x \in V_{0i} \cap A\) we have \(d_{G_i}(x) - \beta m \leq 8 \varepsilon \beta m\);

(ii) For every \(i\) and every \(x \in G_i \setminus V_{0i}\) we have \(|N_{G_i}(x) \cap (V_{0i} \cap A)| \leq 9 \varepsilon \beta m\).

**Proof.** The results will follow by applications of Theorem 8.

(i) For every \(x \in V_{0i} \cap A\) and every edge \(xy\) of \(H_1\) with \(y \notin V_{0i}\), the probability that \(xy\) is assigned to \(G_i\) is exactly \(\beta m/d_{H_1}(x)\). Indeed, with probability 1/2, the endpoint \(x\) of \(xy\) is chosen and then independently with probability \(2 \beta m/d_{H_1}(x)\) we assign \(xy\) to \(G_i\). Observe that since \(y \notin V_{0i}\), if the endpoint \(y\) of \(xy\) was chosen, \(xy\) cannot be assigned to \(G_i\). Thus, the expected size of \(d_{G_i}(x)\) is \(\beta m \frac{d_{H_1 \setminus V_{0i}}(x)}{d_{H_1}(x)}\), which by Lemma 15(i),(iii) is at most \(\beta m\) and at least

\[
\beta m \left(1 - \frac{\gamma d_{V_{0i}}(x) + \zeta n}{d_{G_i}(x) - \zeta n}\right) \overset{(10)}{=} (1 - 7 \varepsilon) \beta m.
\]

Thus by Theorem 8, the probability that the required property fails is at most 2\(rn\exp\left(-\frac{\varepsilon^2 \beta^2 m^2}{3 \beta m}\right) \leq 1/6\).

(ii) By Lemma 15(iii) and (10), we have that \(|N_{H_1}(x) \cap (V_{0i} \cap A)| \leq \gamma |V_{0i}| + \zeta n \leq 4 \varepsilon n\). By Lemma 15(i), every edge \(xy\) of \(H_1\) with \(y \in V_{0i} \cap A\) has probability at most \(\beta m/d_{H_1}(y) \leq 2 \beta m/\gamma n\) of appearing in \(G_i\). Since all such events are independent, by Theorem 8 the probability that (ii) fails is at most \(2rn\exp\left(-\frac{\varepsilon^2 \beta^2 m^2}{24 \varepsilon \beta m}\right) \leq 1/6\).

We now consider the edges of \(H_1\) incident to vertices of \(B\). Observe that on the one hand we have \(\sum |V_{0i}| \geq |B| \frac{\gamma n}{4 \beta m}\). On the other hand, (9) and (10) imply that \(\sum |V_{0i}| \leq \frac{3 \varepsilon n k}{\beta}\). Thus \(|B| \leq 12 \varepsilon n/\gamma\).

For each \(x \in B\), let \(E(x)\) be the set of all edges of the form \(xy\) of \(G\) such that \(xy\) does not belong to any of the \(G_i\)'s or any of the \(H_j\)'s and moreover \(y \notin B \cup V_{0i}\). By definition we have that all the \(E(x)\) are disjoint. Moreover, using \((a'_2)\) and Lemma 15(i)

\[
|E(x)| \geq \delta - (r - \ell_x)(1 + 4 \gamma) \beta m - 3(\gamma + \zeta)n - \frac{12 \varepsilon}{\gamma} n - \varepsilon n \geq \ell_x \beta m.
\]
For each \( x \in B \), we pick a subset \( E'(x) \) of \( E(x) \) of size exactly \( \ell_x \beta m \). We now assign each edge in \( E'(x) \) uniformly at random to the \( \ell_x \) \( G_i \)'s with \( i \in L_x \). Again, we then remove from \( G_i \) any edge that lies within \( V_0i \), so that \( G_i[V_0i] \) is still empty.

**Lemma 18.** With probability at least \( 2/3 \) the following properties hold:

(i) For every \( i \) and every \( x \in V_0i \cap B \) we have \(|d_G(x) - \beta m| \leq \sqrt{\varepsilon \beta m} \);

(ii) For every \( i \) and every \( x \in G_i \setminus V_0i \) we have \(|N_G(x) \cap (V_0i \cup B)| \leq \sqrt{\varepsilon \beta m}/2 \).

**Proof.** The results will follow by applications of Theorem 8.

(i) For every \( x \in B \) and every \( y \notin V_0i \) with \( xy \in E'(x) \), the probability that \( xy \) is assigned to \( G_i \) is exactly \( 1/\ell_x \). Since also \(|E'(x)| - |V_0i| \geq \ell_x \beta m - 3\varepsilon n \) by (10), the expected size of \( d_G(x) \) is at most \( \beta m \) and at least \((1 - \sqrt{\varepsilon/2})\beta m \). So by Theorem 8, the probability of failure is at most \( 2n \exp \left( -\frac{\varepsilon \beta m^2}{12\beta m} \right) \leq 1/6 \).

(ii) We have that \(|V_0i \cap B| \leq |B| \leq 12\varepsilon n/\gamma \) and every edge \( yx \) with \( y \in V_0i \cap B \) has probability either \( 1/\ell_y \) or 0 of appearing in \( G_i \) independently of the others. So

\[
E(\left| N_G(x) \cap (V_0i \cap B) \right|) \leq \frac{|B|}{\ell_y} \leq \frac{12\varepsilon n}{\gamma} \cdot \frac{4\beta m}{\gamma n} \leq \sqrt{\varepsilon} \beta m.
\]

So by Theorem 8, the probability that (ii) fails is at most \( 2n \exp \left( -\frac{\varepsilon \beta m^2}{12} \right) \leq 1/6 \). \( \square \)

Thus we can make a choice of edges which we add to the \( G_i \) so that both properties in Lemmas 17 and 18 hold. This in turn implies that the properties \((a_2.1), (a_2.2)\) as well as the other properties stated at the beginning of the subsection are satisfied.

### 5.4. Adding edges between the clusters of \( G_i \).

Recall that by \((a_2.1)\) every vertex of \( G_i \) has degree \((1 \pm 5\gamma) \beta m \). We would like to almost decompose each \( G_i \) into Hamilton cycles. This would definitely be sufficient to complete the proof of Theorems 6 and 7(ii).

The first step would be to extract from \( G_i \) an \( s \)-regular spanning subgraph \( S_i \) where \( s \) is close to \((1 \pm 5\gamma) \beta m \). Observe that if \( G_i \) does not have such an \( S_i \), then definitely it cannot be almost decomposed into Hamilton cycles. It turns out that at the moment, we cannot guarantee the existence of such an \( S_i \). For example, consider the case when there are no edges between the vertices of \( V_0i \) and the vertices in clusters of the form \( U_{j,i} \) (i.e. all vertices incident to \( V_0i \) lie in the \( V_{j,i} \)). This ‘unbalanced’ structure of \( G_i \) implies that it cannot contain any regular spanning subgraph.

Our aim in this subsection is to use edges from \( H_2 \) in order to transform the \( G_i \)'s so that they have some additional properties which will guarantee the existence of \( S_i \). We will show that adding only edges of \( H_2 \) to the \( G_i \)'s we can for each \( 1 \leq i \leq r \) guarantee the following new properties:

\((a_{2.1}')\) For each \( x \in V(G) \), \( d_G(x) = (1 \pm 15\gamma) \beta m \);

\((a_6)\) For all clusters \( U \neq V \) of \( G_i \) so that \( U^R \) and \( V^R \) are adjacent in \( R \) but not in \( M_i \), we have \(|E_G(U,V)| \geq \beta \gamma dm^2/8k \) and moreover for every \( x \in U \cup V \) we also have \(|N_G(x) \cap (U \cup V)| \leq 15\beta \gamma m/k \).

No edge will be added to more than one of the \( G_i \)'s and so (instead of \((a_5)\)) we will have

\((a_6')\) \( G_1, \ldots, G_r, H_3 \) are edge-disjoint.

Finally, all edges added to \( G_i \) will have both endpoints in distinct clusters of \( G_i \) and moreover for each \( 1 \leq j \leq k' \), no edge will be added to \( G_i \) between the clusters \( U_{j,i} \) and \( V_{j,i} \). In particular, \((a_1), (a_2.2)\) and \((a_4)\) will still hold while instead of \((a_4')\) we will have

\((a_5')\) Every edge of \( G_i \) lies in a pair of the form \((V_0i, U)\), where \( U \) is a cluster of \( G_i \), or a pair of the form \((U, V)\), where \( U \) and \( V \) are clusters of \( G_i \) with \( U^R \) and \( V^R \) adjacent in \( R \).
For every pair of adjacent clusters $U$ and $V$ of $R$, we will distribute the edges in $E_{H_2}(U, V)$ to the $G_i$ so that the following lemma holds. It is then an immediate consequence that all of the above properties are satisfied.

**Lemma 19.** Let $U$ and $V$ be adjacent clusters of $R$. Then we can assign some of the edges of $H_2$ between $U$ and $V$ to the $G_i$ so that every edge is assigned to at most one $G_i$ and moreover

(i) If $UV$ is an edge of $M_i$, then no edge is assigned to $G_i$. Otherwise, at least $\beta \gamma dm^2/8k$ edges are assigned to $G_i$ and none of these edges has an endvertex in $(U \setminus U(i)) \cup (V \setminus V(i))$;

(ii) For every $x \in U(i) \cup V(i)$ at most $10\beta \gamma m/k$ edges incident to $x$ are assigned to $G_i$.

**Proof.** Given such $U, V$, we assign every edge of $E_{H_2}(U, V)$ independently and uniformly at random among the $G_i$’s. If an edge assigned to $G_i$ is incident to $(U \setminus U(i)) \cup (V \setminus V(i))$ it is discarded. If moreover $UV$ is an edge of $M_i$, then all edges assigned to $G_i$ are discarded.

Since $(U, V)_{G'}$ is $\varepsilon$-regular of density at least $d$, Lemma 15(vii) implies that $|E_{H_2}(U, V)| \geq \gamma dm^2/2$ and so by Theorem 8, the number of edges assigned to each $G_i$ is with high probability at least $\gamma dm^2/4r \geq \beta \gamma dm^2/4k$. (The last inequality follows from (9).) To prove (i), it is enough to show that $(if UV$ is not an edge of $M_i then$) at most half of these edges are discarded. Since $|U \setminus U(i)|, |V \setminus V(i)| \leq 2\varepsilon m$, there are at most $4\varepsilon m^2$ such edges which are incident in $G$ to a vertex of $(U \setminus U(i)) \cup (V \setminus V(i))$. Of those, with high probability at most $5\varepsilon m^2/r \leq 25\varepsilon \beta m^2/k$ are assigned to $G_i$ and are thus discarded. To complete the proof, observe that by Lemma 15(v) every vertex $x \in U$ has $|N_{H_2}(x) \cap V| \leq 3\gamma m/2$ (and similarly for every vertex $x \in V$), so by Theorem 8 with high probability no vertex of $G_i$ is incident to more than $2\gamma m/r \leq 10\beta \gamma m/k$ assigned edges. \hfill \Box

5.5. **Finding the regular subgraph** $S_i$. Our aim in this subsection is to show that each $G_i$ contains a regular spanning subgraph $S_i$ of even degree $s := (1 - 15\gamma) \beta m$. Moreover, for every cluster $V$ all its vertices have most of their neighbours in the cluster that $V$ is matched to in $M_i$ (see Lemma 20).

To prove this lemma, we proceed as follows: A result of Frieze and Krivelevich [3] (based on the max-flow min-cut theorem) implies that every pair $(U_{j,i}, V_{j,i})$ contains a regular subgraph of degree close to $\beta m$. However, the example in the previous subsection shows that it is not possible to combine these to an $s$-regular spanning subgraph of $G_i$ due to the the existence of the vertices in $V_{0i}$. So in Lemma 21 we will first find a subgraph $T_i$ of $G_i$ where the vertices of $V_{0i}$ have degree $s$, every non-exceptional vertex has small degree in $T_i$ and moreover each pair $(U_{j,i}, V_{j,i})$ will be balanced with respect to $T_i$ in the following sense: the sum of the degrees of the vertices of $U_{i,j}$ in $T_i$ is equal to the sum of the degrees of the vertices of $V_{i,j}$ in $T_i$. We can then use the following generalization (Lemma 22, proved in [8]) of the result in [3]: in each pair $(U_{j,i}, V_{j,i})$ we can find a subgraph $\Gamma_{j,i}$ with prescribed degrees (as long as the prescribed degrees are not much smaller than $\beta m$). We then prescribe these degrees so that together with those in $T_i$ they add up to $s$. So the union of the $\Gamma_{j,i}$ (over all $1 \leq j \leq k'$) and $T_i$ yields the desired $s$-regular subgraph $S_i$. Note that since $S_i$ is regular, $(U_{j,i}, V_{j,i})$ is balanced with respect to $S_i$ in the above sense (i.e. replacing $T_i$ with $S_i$). Also, the pair will clearly be balanced with respect to $\Gamma_{j,i}$. This explains why we needed to ensure that the pair is also balanced with respect to $T_i$.

**Lemma 20.** For every $1 \leq i \leq r$, $G_i$ contains a subgraph $S_i$ such that

(i) $S_i$ is $s$-regular, where $s := (1 - 15\gamma) \beta m$ is even;

(ii) For every $1 \leq j \leq k'$ and every $x \in U_{j,i}$ we have $|N_{S_i}(x) \setminus V_{j,i}| \leq \eta \beta m$. Similarly, $|N_{S_i}(x) \setminus U_{j,i}| \leq \eta \beta m$ for every $x \in V_{j,i}$.

As discussed above, to prove Lemma 20 we will show that every $G_i$ contains a subgraph $T_i$ with the following properties:
Lemma 21. Each $G_i$ contains a spanning subgraph $T_i$ such that

(i) Every vertex $x$ of $V_{0i}$ has degree $s$;
(ii) Every vertex $y$ of $G_i \setminus V_{0i}$ has degree at most $\eta \beta m$;
(iii) For every $1 \leq j \leq k'$, we have $\sum_{x \in U_j} d_T(x) = \sum_{x \in V_j} d_T(x)$;
(iv) For every $1 \leq j \leq k'$, we have $E_{T_i}(U_{j,i}, V_{j,i}) = \emptyset$.

Having proved this lemma, we can use the following result from [8] to deduce the existence of $S_i$.

Lemma 22. Let $0 < 1/m' \ll \varepsilon \ll \beta' \ll \eta \ll \eta' \ll 1$. Suppose that $\Gamma = (U, V)$ is an $(\varepsilon, \beta')$-super-regular pair where $|U| = |V| = m'$. Define $\tau := (1 - \eta')\beta' m'$. Suppose we have a non-negative integer $x_u \leq \eta \beta m'$ associated with each $u \in U$ and a non-negative integer $y_v \leq \eta \beta m'$ associated with each $v \in V$ such that $\sum_{u \in U} x_u = \sum_{v \in V} y_v$. Then $\Gamma$ contains a spanning subgraph $\Gamma'$ in which $\tau - x_u$ is the degree of each $u \in U$ and $\tau - y_v$ is the degree of each $v \in V$.

Proof of Lemma 20. To derive Lemma 20 from Lemmas 21 and 22, recall that by $(a_2')$ for each $1 \leq j \leq k'$ the pair $(U_{j,i}, V_{j,i})$ is $(2\varepsilon, (1 - 4\gamma)\beta)$-super-regular. Thus we can apply Lemma 22 to $(U_{j,i}, V_{j,i})$ with $2\eta$ playing the role of $\eta$ in the lemma, $\beta' := (1 - 4\gamma)\beta$, $\eta' := 1 - \frac{1 - 15\gamma}{(1 - 4\gamma)(1 - 2\gamma)}$, $m' := (1 - 2\varepsilon)m$, $x_u = d_{T_j}(u)$ for every $u \in U_{j,i}$ and $y_v = d_{T_j}(v)$ for every $v \in V_{j,i}$. Observe that with this value of $\eta'$, we have $\tau = (1 - 15\gamma)\beta m = s$. Lemma 21(ii) implies that for each $u \in U_{j,i}$ and each $v \in V_{j,i}$ we have $2\eta \beta m' = 2\eta(1 - 4\gamma)(1 - 2\varepsilon)\beta m \geq \eta \beta m \geq x_u, y_v$. Lemma 21(iii) implies that $\sum_{u \in U} x_u = \sum_{v \in V} y_v$. Thus the conditions of Lemma 22 hold and we obtain a subgraph $\Gamma_{j,i}$ of $(U_{j,i}, V_{j,i})$ in which every $u \in U_{j,i}$ has degree $s - x_u$ and every $v \in V_{j,i}$ has degree $s - y_v$. It follows from Lemma 21(i),(ii) and (iv) that $S_i = T_i \cup \left( \bigcup_{j=1}^{k'} \Gamma_{j,i} \right)$ is as required in Lemma 20.

Proof of Lemma 21. We give an algorithmic construction of $T_i$. We begin by arbitrarily choosing $s$ edges (of $G_i$) incident to each vertex $x$ of $V_{0i}$. Recall that by $(a_{2.2})$ this means that every vertex of $G_i \setminus V_{0i}$ currently has degree at most $\sqrt{\varepsilon} \beta m$. Let us write $u_{j,i} := \sum_{x \in U_{j,i}} d_{T_i}(x)$ and $v_{j,i} := \sum_{x \in V_{j,i}} d_{T_i}(x)$. Note that these values will keep changing as we add more edges from $G_i$ into $T_i$ and we currently have $|u_{j,i} - v_{j,i}| \leq \sqrt{\varepsilon} \beta m^2$.

Step 1. By adding at most $k'$ more edges, we may assume that for every $1 \leq j \leq k'$, $u_{j,i} - v_{j,i}$ is even.

To prove that this is possible, take any $j$ for which $u_{j,i} - v_{j,i}$ is odd and observe that there is a $j' \neq j$ for which $u_{j',i} - v_{j',i}$ is also odd. This holds because $s$ is even and so there is an even number of edges between $V_{0i}$ and $G_i \setminus V_{0i}$. Let $V$ be a cluster of $R$ which is a common neighbour (in $R$) of $U_{j,i}^R$ and $U_{j',i}^R$, and which is distinct from $V_{j,i}^R$ and $V_{j',i}^R$. The existence of $V$ is guaranteed by the degree conditions of $R$ (see Lemma 13(i)). Now we take an edge of $G_i$ between $V(i)$ and $U_{j,i}$ not already added to $T_i$ and add it to $T_i$. We also take an edge of $G_i$ between $V(i)$ and $U_{j',i}$ not already added to $T_i$ and add it to $T_i$. This makes the differences for $j$ and $j'$ even and preserves the parity of all other differences. So we can perform Step 1.

In each subsequent step, we will take two clusters $U$ and $V$ of $G_i$ and add several edges between them to $T_i$; these edges are chosen from the edges of $G_i$ which are not already used. The clusters $U^R$ and $V^R$ will be adjacent in $R$ but not in $M_i$, so condition (iv) will remain true. We will only add at most $\beta \gamma dm^2/20k$ edges at each step and we will never add edges between $U$ and $V$ more than twice. Condition $(a_6)$ guarantees that we have enough edges for this. (Recall that we have already added at most $k'$ edges between each pair of clusters.) At the end of all these steps condition (iii) will hold. Moreover, we will guarantee that no cluster $U$ is used in more than $2\eta k$ of these steps and so by $(a_6)$ the
degree of each vertex in $T_j$ will not be increased by more than $20\beta \eta \gamma m \ll \eta \beta m$ and so condition (ii) will also be satisfied.

We call a cluster $U$ of $G_i$ bad if it is already used in more than $\eta k$ of the above steps. We will also guarantee that the number of the above steps is at most $\eta^2 k^2/2$. Since in each step we use two clusters, this will imply that at each step there are at most $\eta k$ bad clusters.

Let us now show how all the above can be achieved. Let us take a $j$ for which $u_{j,i} \neq v_{j,i}$. (The case $u_{j,i} > v_{j,i}$ is identical and will thus be omitted.) Since by Lemma 13 the minimum degree of $R$ is at least $(\delta/n - 2d)k/\beta$ and since there are no more than $1/\beta$ parallel edges between any two vertices of $R$, it follows that there are at least $(\delta/n - 1/2 - 2d)k \geq \alpha k/2$ indices $j'$ such that $U_{j,i}^{R}$ is adjacent to both $U_{j,i}^{R'}$ and $V_{j,i}^{R}$ in $R$. Since there are at most $\eta k$ bad clusters, there are at least $\alpha k/3$ indices $j'\neq j$ such that $U_{j,i}^{R}$ is adjacent to both $U_{j,i}^{R'}$ and $V_{j,i}^{R}$ in $R$ and moreover none of $U_{j,i}^{R'}$ and $V_{j,i}^{R}$ is bad. As long as $v_{j,i} - u_{j,i} > \beta \gamma d m^2/10k$, we add exactly $\beta \gamma d m^2/20k$ edges between $U_{j,i}^{R}$ and $U_{j,i}^{R'}$ and exactly $\beta \gamma d m^2/20k$ edges between $V_{j,i}^{R}$ and $V_{j,i}^{R'}$. Note that this decreases the difference $v_{j,i} - u_{j,i}$ and leaves all other differences the same. Finally, if $0 < v_{j,i} - u_{j,i} < \beta \gamma d m^2/10k$ then we carry out the same step except that we add $(v_{j,i} - u_{j,i})/2$ edges between $U_{j,i}^{R}$ and $U_{j,i}^{R'}$ and between $U_{j,i}^{R}$ and $U_{j,i}^{R'}$ instead. (Recall that Step 1 guarantees that $v_{j,i} - u_{j,i}$ is even.) As observed at the beginning of the proof, the initial difference between $u_{j,i}$ and $v_{j,i}$ is at most $\sqrt{\varepsilon \beta m^2}$. This might have increased to at most $2\sqrt{\varepsilon \beta m^2}$ after performing Step 1. Thus it takes at most $20\sqrt{\varepsilon k/\gamma d} + 1 \leq \eta k$ steps to make $u_{j,i}$ and $v_{j,i}$ equal and so we may choose a different index $j'$ in each of these steps.

We repeat this process for all $1 \leq j \leq k'$. Obviously, (iii) holds after we have considered all such $j$'s. It remains to check that all the conditions that we claimed to be true throughout the process are indeed true. As for each $j$ it takes at most $\eta k$ steps to make $u_{j,i}$ and $v_{j,i}$ equal, the total number of steps is at most $\eta^2 k^2/2$. Since moreover, a cluster $U_{j,i}$ or $V_{j,i}$ is used in a step only when $j$ is considered or when it is not bad, it is never used in more than $2\eta k$ steps, as promised.

5.6. Choosing an almost 2-factor decomposition of $S_i$. Since each $S_i$ is regular of even degree, by Theorem 10 we can decompose it into 2-factors. Our aim will be to use the edges of $H_{j,i}$ to transform each 2-factor in this decomposition into a Hamilton cycle. To achieve this, we need each 2-factor in the decomposition to possess some additional properties. Firstly, we would like each 2-factor to contain $o(n)$ cycles. To motivate the second property, note that by Lemma 20(ii), most edges of $S_i$ go between pairs of clusters $(U_{j,i}, V_{j,i})$. So one would expect that this is also the case for a typical 2-factor $F$. We will need the following stronger version of this property: for every pair $(U_{j,i}, V_{j,i})$ of clusters of $G_i$ and every vertex $u \in U_{j,i}$, most of its $S_i$-neighbours in $V_{j,i}$ have both their $F$-neighbours in $U_{j,i}$ (and similarly for every $v \in V_{j,i}$). We will also need the analogous property with $S_i$ replaced by $H_{j,i}$.

The following lemma tells us that we can achieve the above properties if we only demand an almost 2-factor decomposition.

**Lemma 23.** $S_i$ contains at least $(1 - \sqrt{\varepsilon}) \beta m \gamma n$ edge-disjoint 2-factors such that for every such 2-factor $F$ the following hold:

(i) $F$ contains at most $n/\log n^{1/3}$ cycles;

(ii) For every $1 \leq j \leq k'$ and every $u \in U_{j,i}$, the number of $H_{j,i}$-neighbours of $u$ in $V_{j,i}$ which have an $F$-neighbour outside $U_{j,i}$ is at most $\gamma^3 \beta m$ (and similarly for the $H_{j,i}$-neighbours in $U_{j,i}$ of each $v \in V_{j,i}$).
(iii) For every $1 \leq j \leq k'$ and every $u \in U_{j,i}$, the number of $S_i$-neighbours of $u$ in $V_{j,i}$ which have an $F$-neighbour outside $U_{j,i}$ is at most $\gamma^3 \beta m$ (and similarly for the $S_i$-neighbours in $U_{j,i}$ of each $v \in V_{j,i}$).

The proof of Lemma 23 will rely on the following lemma from [8]. This lemma is in turn based on a result in [7] whose proof relies on a probabilistic approach already used in [3].

A 1-factor in an oriented graph $D$ is a collection of disjoint directed cycles covering all the vertices of $D$.

**Lemma 24.** Let $0 < \theta_1, \theta_2, \theta_3 < 1/2$ be such that $\theta_1/\theta_3 < \theta_2$. Let $D$ be a $\theta_3 n$-regular oriented graph whose order $n$ is sufficiently large. Suppose $A_1, \ldots, A_{5n}$ are sets of vertices in $D$ with $|A_i| \geq n^{1/2}$. Let $H$ be an oriented subgraph of $D$ such that $d_H^+(x), d_H^-(x) \leq \theta_1 n$ for all $x \in A_i$ and each $t$. Then $D$ has a 1-factor $F$ such that

(i) $F$ contains at most $n/(\log n)^{1/5}$ cycles;

(ii) For each $t$, at most $\theta_2 |A_t|$ edges of $H \cap F$ are incident to $A_t$.

**Proof of Lemma 23.** We begin by choosing an arbitrary orientation $D$ of $S_i$ with the property that every vertex has indegree and outdegree equal to $s/2$. The existence of such an orientation follows e.g. from Theorem 10. We repeatedly extract 1-factors of $D$ satisfying the properties of Lemma 23 as follows: Suppose we have extracted some 1-factors from $D$ and we are left with a $\theta_3 n$-regular oriented graph $D$, where $\theta_3 \geq \sqrt{3} \beta m/4n$.

For the sets $A_t$, we take all sets of the form $N_{H_{3,i}}(u) \cap V_{j,i}$ and all sets of the form $N_{S_i}(v) \cap V_{j,i}$ (for all $u \in U_{j,i}$ and $j = 1, \ldots, k'$) as well as all sets of the form $N_{H_{3,i}}(v) \cap U_{j,i}$ and all sets of the form $N_{S_i}(v) \cap U_{j,i}$ (for all $v \in V_{j,i}$ and $j = 1, \ldots, k'$). Even though the number of these sets is less than $5n$, this is not a problem as for example we might repeat each set several times. Lemmas 16(ii) and 20(ii) imply that these sets have size at least $\gamma \beta m/6 \gg n^{1/2}$.

For the subgraph $H$ of $D$ we take the graph consisting of all those edges of $S_i$ which do not belong to some pair $(U_{j,i}, V_{j,i})$. Then $d_H^+(x), d_H^-(x) \leq \theta_1 n$ for all $x \in A_t$ (and each $t$), where by Lemma 20(ii) we can take $\theta_1 = \eta \beta m/n$.

Thus, taking $\theta_2 = \gamma^3$ all conditions of Lemma 24 are satisfied and so we obtain a 1-factor $F$ of $D$ satisfying all properties of Lemma 23. (The fact that $s \leq \beta m$ and Lemma 16(iii) imply that the $A_t$ have size at most $\beta m$ and so $F$ satisfies Lemma 23(ii) and (iii).) It follows that we can keep extracting such 1-factors for as long as the degree of $D$ is at least $\sqrt{3} \beta m/4$ and in particular we can extract at least $(1 - \sqrt{3}) \beta m/2$ such 1-factors as required.

5.7. **Transforming the 2-factors into Hamilton cycles.** To finish the proof it remains to show how we can use (for each $i$) the edges of $H_{3,i}$ to transform each of the 2-factors of $S_i$ created by Lemma 23 into a Hamilton cycle. By Lemma 23, this will imply that the total number of edge-disjoint Hamilton cycles we construct is $1 - \sqrt{3} \beta m/2$, which suffices to prove Theorems 6 and 7(ii). To achieve the transformation of each 2-factor into a Hamilton cycle, we claim that it is enough to prove the following theorem. In conditions (iv) and (v) of the theorem we say that a pair of clusters $(A_i, A_j)$ of a graph $X$ is *weakly $(\varepsilon, \varepsilon')$-regular* in a subgraph $H$ of $X$ if for every $U \subseteq A_i, V \subseteq A_j$ with $|U|, |V| \geq \varepsilon m$, there are at least $\varepsilon' m^2$ edges between $U$ and $V$ in $H$.

Roughly speaking, we will apply the following theorem successively to the 2-factors $F$ in our almost-decomposition of $S_i$ and where $H$ is the union of $H_{3,i}$ together with some additional edges incident to $V_{0i}$. However, this does not quite work – between successive applications of the theorem we will also need to add edges to $H$ which were removed from a previous 1-factor $F$ when transforming $F$ into a Hamilton cycle.
Theorem 25. Let \(1/n \ll 1/k \leq \varepsilon \ll \beta \ll \gamma \ll 1\). Let \(m\) be an integer such that \((1-\varepsilon)n \leq mk \leq n\). Let \(H\) be a graph on \(n\) vertices and let \(F\) be a 2-factor so that \(F\) and \(H\) have the same vertices but are edge-disjoint. Let \(X := F \cup H\). Let \(A_1, \ldots, A_k\) be disjoint subsets of \(X\) of size \((1-2\varepsilon)n\) and let \(B_1, \ldots, B_{k'}, D_1, \ldots, D_{k'}\) be another enumeration of the \(A_1, \ldots, A_k\). Suppose also that the following hold:

(i) \(F\) contains at most \(n/(\log n)^{1/5}\) cycles;
(ii) For each \(1 \leq i \leq k\) and for each vertex of \(B_i\) the number of \(H\)-neighbours in \(D_i\) having an \(F\)-neighbour outside \(B_i\) is at most \(2\gamma^3\beta m\) (and similarly for the vertices of \(D_i\));
(iii) For every \(1 \leq i \leq k\), the pair \((B_i, D_i)_H\) is \((3\varepsilon, \gamma\beta/6)\)-super-regular;
(iv) For every \(1 \leq i \leq k\) and every \(A_i\), there are at least \((1+\alpha)k'\) distinct \(j\)'s with \(1 \leq j \leq k\) such that \((A_i, A_j)\) is weakly \((\varepsilon, \varepsilon^3/k)\)-regular in \(H\);
(v) For every \(1 \leq i < j \leq k\), if there is an edge in \(X\) between \(A_i\) and \(A_j\) then \((A_i, A_j)\) is weakly \((\varepsilon, \varepsilon^3/k)\)-regular in \(H\);
(vi) For every vertex \(x \in V(X) \setminus (A_1 \cup \ldots \cup A_k)\), both \(F\)-neighbours of \(x\) belong to \(A_1 \cup \ldots \cup A_k\).

Then there is a Hamilton cycle \(C\) of \(X\) such that \(|E(C) \triangle E(F)| \leq 25m/(\log n)^{1/5}\).

To see that it is enough to prove the above theorem, suppose we have already transformed all 2-factors of \(S_1, \ldots, S_{i-1}\) guaranteed by Lemma 23 into edge-disjoint Hamilton cycles such that for each \(1 \leq j < i \leq \ell - 1\) the Hamilton cycles corresponding to the 2-factors of \(S_j\) lie in \(G \setminus \bigcup_{j' > j} (G_{j'} \cup H_{j,j'})\). Moreover, suppose that we have also transformed \(\ell\) of the 2-factors of \(S_1\), say \(F_1, \ldots, F_\ell\), into edge-disjoint Hamilton cycles \(C_1, \ldots, C_\ell\) such that \(C_j \subseteq G \setminus \bigcup_{j' > j} (G_{j'} \cup H_{j,j'})\) and \(|E(C_j) \triangle E(F_j)| \leq 25m/(\log n)^{1/5}\) for all \(1 \leq j \leq \ell\). Obtain \(H^*_j\) from \(H_{3,j}\) as follows:

\((b_0)\) add all those edges of \(G\) between \(V_0\) and \(V(G) \setminus V_0\) which do not belong to any \(G_{j'} \cup H_{3,j}\) with \(j \geq i\) or to any Hamilton cycle already created.

Suppose that we have inductively defined graphs \(H^*_1, \ldots, H^*_\ell\) such that \(C_j \subseteq H^*_j \cup F_j\) for all \(1 \leq j \leq \ell\). Define \(H^*_{\ell+1}\) as follows:

\((b_1)\) remove all edges in \(E(C_\ell) \setminus E(F_\ell)\) from \(H^*_\ell\);
\((b_2)\) add all edges in \(E(F_\ell) \setminus E(C_\ell)\) to \(H^*_\ell\).

Let \(F_{\ell+1}\) be one of the 2-factors of \(S_j\) as constructed in Lemma 23 which is distinct from \(F_1, \ldots, F_\ell\). Finally, let \(B_j = U_{j,i}\) and \(D_j = V_{j,i}\) for \(1 \leq j \leq k'\). We claim that all conditions of Theorem 25 hold (with \(H^*_{\ell+1}\) and \(F_{\ell+1}\) playing the roles of \(H\) and \(F\)). Indeed, property (i) follows from Lemma 23(i). Since \(N_{H^*_{\ell+1}}(u) \cap V_{j,i} \subseteq (N_{H_{3,i}}(u) \cup N_{S_j}(u)) \cap V_{j,i}\) for every \(u \in U_{j,i}\) (note that this is not necessarily true for \(u \in V_0\)), property (ii) follows from Lemma 23(ii) and (iii). To see that property (iii) holds, recall that by Lemma 16(ii) we have that for every \(1 \leq j' \leq k\) the pair \((B_{j'}, D_{j'})\) is \((5\varepsilon/2, \gamma\beta/5)\)-super-regular. Since also \(|E(C_j) \triangle E(F_j)| \leq 25n/(\log n)^{1/5}\) for each \(1 \leq j \leq \ell\), we have \(|E(H^*_{\ell+1}) \setminus V_0) \setminus \triangle E(H_{3,i} \setminus V_0)| \leq 25n^2/(\log n)^{1/5}\) and so \((B_{j'}, D_{j'})H^*_{\ell+1}\) is \(3\varepsilon\)-regular of density at least \(\gamma\beta/6\). To prove that the pair is even \((3\varepsilon, \gamma\beta/6)\)-super-regular, it suffices to show that for any \(x \in B_{j'}\) we have

\[|N_{H^*_{\ell+1}}(x) \cap D_{j'}| \geq \gamma\beta m/6.\]  \hspace{1cm} (11)

(A bound for the case \(x \in D_{j'}\) will follow in the same way.) To prove (11), suppose that the degree of \(x\) in \((B_{j'}, D_{j'})H^*_{\ell+1}\) was decreased by one compared to \((B_{j'}, D_{j'})H^*_\ell\) due to \((b_1)\). This means that an edge \(xy\) of \((B_{j'}, D_{j'})H^*_\ell\) was inserted into \(C_{j'}\). But since \(F_\ell\) and \(C_{j'}\) are both 2-factors, this means that an edge \(xz\) from \(F_\ell\) will be added to \(H^*_\ell\) when forming \(H^*_{\ell+1}\.\)
Note that \(xz \in E(F_t) \subseteq E(S_t)\) and by our assumption on the degree of \(x\), we have \(z \notin D_J\).
If the degree decreases by two of \(x\), then the argument shows that we will be adding two such edges \(xz_1\) and \(xz_2\) to \(H^*_t\) when forming \(H^*_{t+1}\). But since Lemma 20(ii) implies that \(|N_{S_t}(x) \setminus D_J| \leq \eta \beta m\), this can happen at most \(\eta \beta m\) times throughout the process of constructing \(C_1, \ldots, C_L\). (Here we are also using the fact that the \(F_j\) are edge-disjoint, so we will consider such an edge \(xz\) or \(xz_i\) only once throughout.) So

\[
|N_{H^*_{t+1}}(x) \cap D_J| \geq |N_{H_{3,i}}(x) \cap D_J| - \eta \beta m \geq \gamma(1 - 2\varepsilon)m/5 - \eta \beta m \geq \gamma \beta m/6,
\]

which proves (11) and thus (iii). Property (iv) follows from Lemma 16(i) together with the fact that \(|E(H_{3,i}|V_0)| \Delta E(H^*_{t+1}|V_0)| = o(n^2)\) and the fact that the minimum degree of \(R\) is at least \((1 + \alpha)k/2\beta\) (see Lemma 13). Property (v) follows similarly since by \((a''_1)\) each edge in \(E(F_{t+1}) \subseteq E(G_i)\) between clusters corresponds to an edge of \(R\) and since by Lemma 16(iv) the analogue holds for the edges of \(H_{3,i}\). Property (vi) is an immediate consequence of \((a''_1)\). To see that (vii) holds consider a vertex \(x \in V(X) \setminus (A_1 \cup \ldots \cup A_k)\).

By Lemma 15(i) \(x\) has degree at most \(2\gamma n\) in \(H_3\) and thus in the union of \(H_{3,j}\) with \(j \geq i\). By \((a''_2)\), \(x\) has degree at most \((r - i + 1)(1 + 15\gamma)\beta m\) in the union of the \(G_j\) with \(j \geq i\). The number of Hamilton cycles already constructed is at most \(i(1 - \sqrt{\gamma})\beta m/2\).
Furthermore, \(x\) has at most \(|V_0| \leq 3\varepsilon n\) neighbours in \(V_0\). So altogether the number of edges of \(G\) incident to\(x\) which are not included in \(H^*_{t+1}\) due to \((b_0)\) and \((b_1)\) is at most \(2\gamma n + (r - 1)(1 + 15\gamma)\beta m + 3\varepsilon n \leq \delta - \alpha n/6\), where the inequality follows from the bound on \(\delta\) in (9). So the number of edges incident to \(x\) in \(H^*_{t+1}\) is at least \(\alpha n/6\). Moreover, by Lemma 16(iv) and \((a''_1)\) no neighbour of \(x\) in \(H_{3,i} \cup G_i\) lies in \(V_0\), and thus the same is true for every \(H^*_{t+1}\) neighbour of \(x\).

5.8. Proof of Theorem 25. In the proof of Theorem 25 it will be convenient to use the following special case of a theorem of Ghouila-Houri [4], which is an analogue of Dirac’s theorem for directed graphs.

**Theorem 26 (4).** Let \(G\) be a directed graph on \(n\) vertices with minimum out-degree and minimum in-degree at least \(n/2\). Then \(G\) contains a directed Hamilton cycle.

We will also use the following ‘rotation-extension’ lemma which appears implicitly in [3] and explicitly (but for directed graphs) in [8]. The directed version implies the undirected version (and the latter is also simple to prove directly). Given a path \(P\) with endpoints in opposite clusters of an \(\varepsilon\)-regular pair, the lemma provides a cycle on the same vertex set by changing only a small number of edges.

**Lemma 27.** Let \(0 < 1/m \ll \varepsilon \ll \gamma' < 1\) and let \(G\) be a graph on \(n \geq 2m\) vertices. Let \(U\) and \(V\) be disjoint subsets of \(V(G)\) with \(|U| = |V| = m\) such that for every \(S \subseteq U\) and every \(T \subseteq V\) with \(|S|, |T| \geq \varepsilon m\) we have \(e(S, T) \geq \gamma'|S||T|\). Let \(P\) be a path in \(G\) with endpoints \(x\) and \(y\) where \(x \in U\) and \(y \in V\). Let \(U_P\) be the set of vertices of \(P\) which belong to \(U\) and have all of their \(P\)-neighbours in \(V\) and let \(V_P\) be defined analogously. Suppose that \(|N(x) \cap V_P|, |N(y) \cap U_P| \geq \gamma' m\). Then there is a cycle \(C\) in \(G\) containing precisely the vertices of \(P\) and such that \(C\) contains at most 5 edges which do not belong to \(P\).

**Proof of Theorem 25.** We will give an algorithmic construction of the Hamilton cycle. Before and after each step of our algorithm we will have a spanning subgraph \(H'\) of \(H\) and spanning subgraph \(F'\) of \(X\) which is a union of disjoint cycles and at most one path such that \(H'\) and \(F'\) are edge-disjoint. In each step we will add at most 5 edges from \(H'\) to \(F'\) and remove some edges from \(F'\) to obtain a new spanning subgraph \(F''\). The edges added to \(F'\) will be removed from \(H'\) to obtain the new subgraph \(H''\). It will turn out that the number of steps needed to transform \(F\) into a Hamilton cycle will be at most \(5n/(\log n)^{1/5}\). This will complete the proof of Theorem 25.
To simplify the notation we will always write $H$ and $F$ for these subgraphs of $X$ at each step of the algorithm. Also, let $g(n) := n/(\log n)^{1/5}$. We call all the edges of the initial $F$ original. At each step of the algorithm, we will write $B'_i$ for the set of vertices $b \in B_i$ whose neighbours in the current graph $F$ both lie in $D_i$ and are joined to $b$ by original edges (for each $1 \leq i \leq k'$). We define $D'_i$ similarly. So during the algorithm the size of each $B'_i$ might decrease, but since we delete at most $25g(n)$ edges from the initial $F$ during the algorithm, all but at most $50g(n)$ vertices of the initial $B'_i$ will still belong to this set at the end of the algorithm (and similarly for each $D'_i$).

Since at each step of the algorithm the current $F$ differs from the initial one by at most $25g(n)$ edges (and so at most $25g(n)$ edges have been removed from the initial $H$), we will be able to assume that at each step of the algorithm the following conditions hold.

(a) For each $1 \leq i \leq k'$ each vertex of $B_i$ has at most $3\gamma^3\beta m$ $H$-neighbours in $D_i \setminus D'_i$ (and similarly for the vertices in $D_i$);
(b) For every $1 \leq i \leq k'$, the pair $(B_i, D_i)_H$ is $(4\varepsilon, \gamma\beta/7)$-super-regular;
(c) For every $1 \leq i \leq k$ and every $A_i$, there are at least $(1 + \alpha)k'$ distinct $j$’s with $1 \leq j \leq k$ such that $(A_i, A_j)$ is weakly $(\varepsilon, \varepsilon^3/2k)$-regular in $H$;
(d) For every $1 \leq i < j \leq k$, if there is an edge in $X$ between $A_i$ and $A_j$ then $(A_i, A_j)$ is weakly $(\varepsilon, \varepsilon^3/2k)$-regular in $H$;
(e) Every vertex $x \in V(X) \setminus (A_1 \cup \ldots \cup A_k)$ has degree at least $\alpha n/7$ in $H$ and all $H$-neighbours of $x$ lie in $A_1 \cup \ldots \cup A_k$.

Note that by (a) and (b) we always have
\[
|B'_i|, |D'_i| \geq (1 - \gamma)m. \tag{12}
\]

To see this, suppose that initially we have $|B_i \setminus B'_i| \geq \gamma m/2$. Then by (b) there is a vertex $x \in D_i$ which has at least $\gamma^3\beta m/20 > 3\gamma^3\beta m$ $H$-neighbours in $B_i \setminus B'_i$, contradicting (a). So (12) follows since we have already seen that all but at most $50g(n)$ vertices of the original set $B'_i$ still belong to $B'_i$ at the end of the algorithm.

**Claim 1.** After at most $g(n)$ steps, we may assume that $F$ is still a 2-factor and that for each $1 \leq i \leq k'$ there is a cycle $C_i$ of $F$ which contains at least $\gamma\beta m/9$ vertices of $B'_i$ and at least $\gamma\beta m/9$ vertices of $D'_i$.

Note that we may have $C_i = C_j$ even if $i \neq j$ (and similarly in the later claims). To prove the claim, suppose that $F$ does not contain such a cycle $C_i$ for some given $i$. Let $C$ be a cycle of $F$ which contains an edge $xy$ with $x \in B_i$ and $y \in D_i$. Note that such a cycle exists by (12). Consider the path $P$ obtained from $C$ by removing the edge $xy$. If $x$ has an $H$-neighbour $y'$ on another cycle $C'$ of $F$ such that $y'$ has an $F$-neighbour $x'$ with $x' \in B_i$ then we replace the path $P$ and the cycle $C'$ with the path $x'C'y'Py$. (Note that $x'$ will be one of the neighbours of $y'$ on $C'$.) We view the construction of this path as carrying out one step of the algorithm. Observe that we have only used one edge from $H$ and we have reduced the number of cycles of $F$ by 1 when extending $P$. Let us relabel so that the unique path of $F$ is called $P$ and its endpoints $x$ and $y$ belong to $B_i$ and $D_i$ respectively. Repeating this extension step for as long as possible, we may assume that no $H$-neighbour of $x$ which is not on $P$ has an $F$-neighbour in $B_i$ and similarly no $H$-neighbour of $y$ which is not on $P$ has an $F$-neighbour in $D_i$. In particular, by (a) and (b), $x$ has at least $\gamma\beta m/8$ $H$-neighbours in $V(P) \cap D'_i$, and similarly $y$ has at least $\gamma\beta m/8$ $H$-neighbours in $V(P) \cap B'_i$. By Lemma 27 (applied with $U := B_i$, $V := D_i$, and $G := X$) it follows that we can use at most 5 edges of $H$ to convert $P$ into a cycle $C_i$ (we view this as another step of the algorithm). Note that $C_i$ satisfies the conditions of the claim. Since the number of cycles in $F$ is initially at most $g(n)$ and since a Hamilton cycle certainly would satisfy the claim, the number of steps can be at most $g(n)$. 

Claim 2. After at most \( g(n) \) further steps, we may assume that \( F \) is still a 2-factor and that for each \( 1 \leq i \leq k' \) there is a cycle \( C'_i \) of \( F \) which contains all but at most \( 4\varepsilon m \) vertices of \( B'_i \) and all but at most \( 4\varepsilon m \) vertices of \( D'_i \).

Let \( C'_i \) be a cycle of \( F \) which contains at least \( \gamma\beta m/9 \) vertices of \( B'_i \) and at least \( \gamma\beta m/9 \) vertices of \( D'_i \). Suppose there are at least \( 4\varepsilon m \) vertices of \( B'_i \) not covered by \( C'_i \). Then (b) implies that there is a vertex \( b \in B'_i \), which is not covered by \( C'_i \) and a vertex \( d \in D'_i \) which is covered by \( C'_i \) such that \( b \) and \( d \) are neighbours in \( H \). Let \( C'' \) be the cycle containing \( b \) and let \( x \) be any neighbour of \( b \) on \( C'' \) and \( y \) any neighbour of \( d \) on \( C'_i \). Then removing the edges \( bx \) and \( dy \) and adding the edge \( bd \) we obtain the path \( xC''bdC'_iy \) (see Figure 3).

\[
\begin{array}{c}
\text{Figure 3. Extending } C_i \text{ to include more vertices from } B'_i \cup D'_i.
\end{array}
\]

Since \( x \in D_i \) and \( y \in B_i \) (as \( b \in B'_i \) and \( d \in D'_i \)) we can repeat the argument in the previous claim to extend this path into a larger path if necessary and then close it into a cycle. As long there are at least \( 4\varepsilon m \) vertices of \( B'_i \) not covered by the cycle or at least \( 4\varepsilon m \) vertices of \( C'_i \) not covered by the cycle we can repeat the above procedure to extend this into a larger cycle. Thus we can obtain a cycle \( C''_i \) with the required properties. The bound on the number of steps follows as in Claim 1.

Claim 3. After at most \( g(n) \) further steps, we may assume that \( F \) is still a 2-factor and that for each \( 1 \leq i \leq k' \) there is a cycle \( C''_i \) of \( F \) which contains all vertices of \( B'_i \cup D'_i \).

Let \( C''_i \) be the cycle obtained in the previous claim and suppose there is a vertex \( b \in B'_i \) not covered by \( C''_i \). By (a) and (b) it follows that \( b \) has at least \( \gamma\beta m/8 \) \( H \)-neighbours in \( V(C''_i) \cap D'_i \). Let \( d \) be such an \( H \)-neighbour of \( b \). Repeating the procedure in the proof of the previous claim, we can enlarge \( C''_i \) into a cycle containing \( b \). Similarly we can extend the cycle to include any \( d \in D'_i \), thus proving the claim.

Claim 4. After at most \( g(n) \) further steps, we may assume that \( F \) is still a 2-factor and that for each \( 1 \leq i \leq k' \) there is a cycle \( C'''_i \) of \( F \) which contains all vertices of \( B_i \cup D_i \) and that there are no other cycles in \( F \).

Let \( C'''_i \) be the cycle obtained in the previous claim and let \( x \) be a vertex in \( B_i \) not covered by \( C'''_i \). (The case when some vertex in \( D_i \) is not covered by \( C'''_i \) is similar.) Let \( C \) be the cycle of \( F \) containing \( x \) and let \( y \) and \( z \) be the neighbours of \( x \) on \( C \).

Case 1. \( y \in A_j \) for some \( j \).

It follows from (d) that there are at least \( (1-\varepsilon)m \) vertices of \( A_j \) which have an \( H \)-neighbour in \( B_i \). Also, \( y \) has an \( H \)-neighbour \( w \) satisfying the following:

(i) both \( F \)-neighbours of \( w \) belong to \( A_j \setminus \{y\} \);
(ii) both \( F \)-neighbours of \( w \) have an \( H \)-neighbour in \( B'_i \).

To see that we can choose such a \( w \), suppose first that \( A_j = B_{j'} \) for some \( j' \). Then \( y \) has a set \( N_y \) of at least \( \gamma\beta m/8 \) \( H \)-neighbours in \( D_{j'} \) by (b). By (a), at most \( 3\gamma^3\beta m \) vertices of \( N_y \) do not have both \( F \)-neighbours in \( B_{j'} \). Note that \( y \) cannot be one of these \( F \)-neighbours in \( B_{j'} \) since \( H \) and \( F \) are edge-disjoint. So \( N_y \) contains a set \( N^*_y \) of size \( \gamma\beta m/9 \) so that all vertices in \( N^*_y \) satisfy (i). By (d) at most \( 2\varepsilon m \) of these do not satisfy (ii). The argument for the case when \( A_j = D_{j'} \) for some \( j' \) is identical.
The next step depends on whether \( w \) belongs to \( C''_i, \) or some other cycle \( C' \) of \( F. \) In all cases we will find a path \( P \) from \( x \in B_i \) to a vertex \( y'' \in D_i \) containing all vertices of \( C''_i \cup C. \) We can then proceed as before to find a cycle containing all the vertices of this path.

**Case 1a.** \( w \in C''_i. \)

Let \( y' \) be any one of the \( F\)-neighbours of \( w \). Let \( x' \) be any \( H\)-neighbour of \( y' \) with \( x' \in B_i' \) guaranteed by (ii) (so \( x' \) lies on \( C''_i \)) and let \( y'' \in D_i \) be the \( F\)-neighbour of \( x' \) in the segment of \( C''_i \) between \( x' \) and \( y' \) not containing \( w \). Then we can replace the cycles \( C''_i \) and \( C \) by the path \( xzCywC''_ix'y'C''_iy'' \) by removing the edges \( yx, wy' \) and \( x'y'' \) and adding the edges \( yw \) and \( y'x'. \)

**Case 1b.** \( w \in C. \)

Let \( y' \) be the \( F\)-neighbour of \( w \) in the segment of \( C \) between \( y \) and \( w \) not containing \( x \). Let \( x' \) be any \( H\)-neighbour of \( y' \) with \( x' \in B_i' \) and let \( y'' \) be any \( F\)-neighbour of \( x' \). Note that \( x' \) and \( y'' \) both lie on \( C''_i \) as \( x' \in B_i' \). Then we can replace the cycles \( C''_i \) and \( C \) by the path \( xzCywC''_ix'y'C''_iy'' \) by removing the edges \( yx, wy' \) and \( x'y'' \) and adding the edges \( yw \) and \( y'x' \).

**Case 1c.** \( w \in C' \) for some \( C' \neq C''_i, C''_i \).

Let \( y' \) be any one of the \( F\)-neighbours of \( y \). Let \( x' \) be any \( H\)-neighbour of \( y' \) with \( x' \in B_i' \) and let \( y'' \) be any \( F\)-neighbour of \( x' \). So \( x' \) and \( y'' \) both lie on \( C''_i \). We can replace the cycles \( C''_i, C \) and \( C' \) by the path \( xzCywC''_ix'y'C''_iy'' \) by removing the edges \( yx, wy' \) and \( x'y'' \) and adding the edges \( yw \) and \( y'x' \).

**Case 2.** \( y \in V(X) \setminus (A_1 \cup \cdots \cup A_k). \)

Let \( A \) be a cluster so that \( y \) has a set \( N_y \) of at least \( \alpha^2 m \) \( H\)-neighbours in \( A' \) (if \( A = B_j \) for some \( j \), then \( A' \) denotes the set \( B_j' \) and similarly if \( A = D_j \)). Such an \( A \) exists since otherwise \( y \) would have at most \( \gamma n + \alpha^2 n \) neighbours in \( H \) by (12) and the second part of (e). But this would contradict the lower bound of at least \( \alpha n/7 \) \( H\)-neighbours given by (e). Without loss of generality, we may assume that \( A = B_j \) for some \( j \), the argument for \( A = D_j \) is identical. Then by (e) there is an index \( s \neq j \) so that either (c1) or (c2) holds:

(1) the pairs \((B_s, D_j)\) and \((D_s, B_i)\) are weakly \((\varepsilon, \varepsilon_3/2k)\)-regular in \( H \);

(2) the pairs \((D_s, D_j)\) and \((B_s, B_i)\) are weakly \((\varepsilon, \varepsilon_3/2k)\)-regular in \( H \).

We may assume that (c1) holds, the argument for (c2) is identical. For convenience, we fix an orientation of each cycle of \( F \). Given a vertex \( v \) on a cycle of \( F \), this will enable us to refer to the successor \( v^+ \) of \( v \) and predecessor \( v^- \) of \( v \). In particular, let \( N_y^+ \) be the successors of the vertices in \( N_y \) on \( C''_j \) and let \( N_y^- \) be the predecessors. So \( N_y^+, N_y^- \subseteq D_j \) and \(|N_y^-|, |N_y^+| \geq \alpha^2 m \).

Also, let \( B''_s \) be the subset of vertices \( v \) of \( B'_s \) so that both \( F\)-neighbours \( v^- \) and \( v^+ \) of \( v \) have at least five \( H\)-neighbours in \( B_i' \). Since \( v^-, v^+ \in D_s \), (c1) and (12) together imply that \(|B''_s| \geq m/2 \). Two application of (c1) to \((B_s, D_j)\) now imply that there is a vertex \( w \in N_y \) so that both \( w^+ \) and \( w^- \) have at least one \( H\)-neighbour in \( B''_s \) (more precisely, apply (c1) to the subpairs \((B''_s, N_y^+)\) and \((B''_s, N_y^-)) \).

Suppose first that \( C \neq C''_i \). Then let \( w_+ := w^+ \) and we can obtain a path \( P_1 \) with the same vertex set as \( C \cup C''_i \) by defining \( P_1 := xzCywC''_iw_+ \). If \( C = C''_i \), then let \( w_+ \) be the \( C\)-neighbour of \( w \) on the segment of \( C \) between \( w \) and \( y \) which does not contain \( x \) and let \( P_1 := xzCywC''_iw_+ \).

Let \( v \) be the \( H\)-neighbour of \( w_+ \) in \( B''_s \) (guaranteed by the definition of \( w \)). Note that \( v \neq y \) and \( v \neq w \) (as \( s \neq j \)). Suppose first that \( C''_s \neq C''_i \). Then we let \( v_+ := v^+ \) and define the path \( P_2 := xP_1w_+vC''_sv_+ \). If \( C''_s = C''_i \) or \( C''_s = C \), then all vertices of \( C''_s \) already
lie on $P_1$ and we let $v_\uparrow$ be the $P_1$-neighbour of $v$ on the segment of $P_1$ towards $w_\uparrow$ and let $P_2 := xP_1v_\uparrow P_1v_\uparrow$.

Now let $u$ be an $H$-neighbour of $v_\uparrow$ in $B'_i$. (To see the existence of $u$, note that $v_\uparrow$ is one of the $F$-neighbours of $v$ in the definition of $B''_s$ since $v \neq u, v$.) If $C_i \neq C''_i$ and $C''_i \neq C''_s$, then let $u_\uparrow := u^+$ and define the path $P_3 := xP_2u_\uparrow C''_i u_\uparrow$. If $C''_i = C''_i$ or $C_i = C''_s$, then all the vertices of $C''_s$ already lie on $P_2$. Since at most 2 edges of $C''_i$ do not lie on $P_2$ and since $v_\uparrow$ has at least five $H$-neighbours in $B'_i$ by definition of $B''_s$, we can choose $u$ in such a way that its $P_2$-neighbours both lie in $D_i$. We now let $u_\uparrow \in D_i$ be the $P_2$-neighbour of $u$ on the segment of $P_2$ towards $v_\uparrow$, and let $P_3 := xP_2u_\uparrow P_2u_\uparrow$. Note that $P_3$ has endpoints $x \in B_i$ and $u_\uparrow \in D_i$ and contains all vertices of $C''_i \cup C$, as desired. (We count the whole construction of $P_3$ as one step of the algorithm.) This completes Case 2.

Repeating this procedure, for each $i$ we can find a cycle $C''_i$ which contains all vertices of $B_i \cup D_i$. Property (vi) of Theorem 25 and the second part of (e) together imply that no cycle in the 2-factor $F$ thus obtained can consist entirely of vertices in $V(X) \setminus (A_1 \cup \cdots \cup A_k)$ and so the $C''_i$ are the only cycles in $F$.

**Claim 5.** By relabeling if necessary, we may assume that for every $1 \leq i \leq k'$, the pair $(B_i, D_{i+1})$ is weakly $(\varepsilon, \varepsilon^3/2k)$-regular in $H$ (where $D_{k'+1} := D_1$).

For each $1 \leq i \leq k'$ we relabel $B_i$ and $D_i$ into $D_i$ and $B_i$ respectively with probability 1/2 independently. Property (c) together with Theorem 8 imply that with high probability for each $1 \leq i \leq k'$ there are at least $(1 + \alpha/2)k'/2$ indices $j$ and least $(1 + \alpha/2)k'/2$ indices $j'$ with $1 \leq j, j' \leq k'$ and $j \neq j'$ such that each $(B_i, D_j)$ and each $(B_j, D_i)$ are weakly $(\varepsilon, \varepsilon^3/2k)$-regular in $H$. Fix such a relabeling. Define a directed graph $J$ on vertex set $[k']$ by joining $i$ to $j$ by a directed edge from $i$ to $j$ if and only if the pair $(B_i, D_j)$ is weakly $(\varepsilon, \varepsilon^3/2k)$-regular in $H$. Then $J$ has minimum out-degree and minimum in-degree at least $(1 + \alpha/2)k'/2$ and so by Theorem 26 it contains a directed Hamilton cycle. Claim 5 now follows by reordering the indices of the $B_i$’s and $D_i$’s so that they comply with the ordering in the Hamilton cycle.

**Claim 6.** For each $1 \leq j \leq k'$, after at most $j$ steps, we may assume that $F$ is a union of cycles together with a path $P_j$ such that $P_j$ has endpoints $x \in D_1$ and $y_j \in B_j$, where $y_j$ has an $H$-neighbour in $D'_{j+1}$, and $P_j$ covers all vertices of $(B_1 \cup D_1) \cup \cdots \cup (B_j \cup D_j)$. Furthermore, for every $1 \leq i \leq k'$, either $P_j$ covers all vertices of $C''_i$ or $V(P_j) \cap V(C''_i) = \emptyset$.

To prove this claim we proceed by induction on $j$. For the case $j = 1$ observe that by Claim 5 there are at least $(1 - \varepsilon)m$ vertices of $B_1$ which have at least one $H$-neighbour in $D_2$. Of those, there is at least one vertex $y_1$ which belongs to $B'_1$. Let $x$ be any $F$-neighbour of $y_1$ (so $x \in D_1$) and remove the edge $xy_1$ from $C''_i$ to obtain the path $P_1$. Having obtained the path $P_j$, let $x_{j+1}$ be an $H$-neighbour of $y_j$ in $D'_{j+1}$ (we count the construction of each $P_j$ as one step of the algorithm).

**Case 1.** $P_j$ covers all vertices of $C''_i$.

In this case, let $z_{j+1}$ be the neighbour of $x_{j+1}$ on $P_j$ in the segment of $P_j$ between $x_{j+1}$ and $y_j$ and let $Q_{j+1}$ be the path obtained from $P_j$ by adding the edge $y_jx_{j+1}$ and removing the edge $x_{j+1}z_{j+1}$. Observe that the endpoints of the path are $x \in D_1$ and $z_{j+1} \in B_{j+1}$ (but $z_{j+1}$ need not have an $H$-neighbour in $D'_{j+2}$). By (a) and (b) $z_{j+1}$ has at least $\gamma \beta m/8$ $H$-neighbours $w_{j+1}$ in $D'_{j+1}$. For each such $H$-neighbour $w_{j+1}$, let $w'_{j+1}$ be the unique neighbour of $w_{j+1}$ on $Q_{j+1}$ in the segment of $Q_{j+1}$ between $w_{j+1}$ and $z_{j+1}$. So $w'_{j+1} \in B_{j+1}$. Since by the previous claim at most $\varepsilon m$ vertices of $B_{j+1}$ do not have an $H$-neighbour in $D'_{j+2}$, we can choose a $w_{j+1}$ so that $w'_{j+1}$ has an $H$-neighbour in $D'_{j+2}$.
We can then take \( y_{j+1} := w'_{j+1} \) and obtain \( P_{j+1} \) from \( Q_{j+1} \) by adding the edge \( z_{j+1}w_{j+1} \) and removing the edge \( w_{j+1}w'_{j+1} \).

**Case 2.** \( V(P_j) \cap V(C''_{j+1}) = \emptyset \).

In this case, we let \( z_{j+1} \) be any \( F \)-neighbour of \( x_{j+1} \) and let \( Q_{j+1} \) be the path obtained from \( P_j \) and \( C''_{j+1} \) by adding the edge \( y_jx_{j+1} \) and removing the edge \( x_{j+1}z_{j+1} \). Observe that the endpoints of the path are \( x \in D_1 \) and \( z_{j+1} \in B_{j+1} \) and so this case can be completed as the previous case.

By the case \( j = k' \) of the previous claim we may assume that we now have a path \( P := P_{k'} \) which covers all vertices of \( A_1 \cup \cdots \cup A_k \) and has endpoints \( x \in D_1 \) and \( y := y_{k'} \in B_{k'} \) where \( y \) has an \( H \)-neighbour in \( D'_1 \). Moreover, \( P \) contains all vertices of each \( C''_i \) and so by Claim 4 it must be a Hamilton path. Now let \( z \) be any \( H \)-neighbour of \( y \) with \( z \in D'_1 \) and let \( w \) be the neighbour of \( z \) in the segment of \( P \) between \( z \) and \( y \). Let \( Q \) be the path obtained from \( P \) by removing the edge \( wz \) and adding the edge \( yz \). So \( Q \) is a path on the same vertex set as \( P \) with endpoints \( x \in D_1 \) and \( w \in B_1 \) (we count the construction of \( Q \) as another step of the algorithm). But then we can apply Lemma 27 to transform \( Q \) into a Hamilton cycle in one more step, thus completing the proof of Theorem 25.

\[ \square \]

6. Acknowledgment

We would like to thank Andrew Treglown for helpful discussions.
