THE EXISTENCE OF DESIGNS VIA ITERATIVE ABSORPTION:
HYPERGRAPH $F$-DESIGNS FOR ARBITRARY $F$

STEFAN GLOCK, DANIELA KÜHN, ALLAN LO AND DERYK OSTHUS

ABSTRACT. We solve the existence problem for $F$-designs for arbitrary $r$-uniform hypergraphs $F$. This implies that given any $r$-uniform hypergraph $F$, the trivially necessary divisibility conditions are sufficient to guarantee a decomposition of any sufficiently large complete $r$-uniform hypergraph into edge-disjoint copies of $F$, which answers a question asked e.g. by Keevash. The graph case $r = 2$ was proved by Wilson in 1975 and forms one of the cornerstones of design theory. The case when $F$ is complete corresponds to the existence of block designs, a problem going back to the 19th century, which was recently settled by Keevash. In particular, our argument provides a new proof of the existence of block designs, based on iterative absorption (which employs purely probabilistic and combinatorial methods).

Our main result concerns decompositions of hypergraphs whose clique distribution fulfills certain regularity constraints. Our argument allows us to employ a ‘regularity boosting’ process which frequently enables us to satisfy these constraints even if the clique distribution of the original hypergraph does not satisfy them. This enables us to go significantly beyond the setting of quasirandom hypergraphs considered by Keevash. In particular, we obtain a resilience version and a decomposition result for hypergraphs of large minimum degree.

1. Introduction

The term ‘combinatorial design’ usually refers to a system of finite sets which satisfies some specified balance or symmetry condition. Some well known examples include balanced incomplete block designs, projective planes, Latin squares and Hadamard matrices. These have applications in many areas such as finite geometry, statistics, experiment design and cryptography.

1.1. Background. In this paper,1 we consider block designs and more generally $F$-designs, which can be conveniently defined using graph theoretical terminology. A hypergraph $G$ is a pair $(V, E)$, where $V = V(G)$ is the vertex set of $G$ and the edge set $E$ is a set of subsets of $V$. We often identify $G$ with $E$, in particular, we let $|G| := |E|$. We say that $G$ is an $r$-graph if every edge has size $r$. We let $K_{n}^{(r)}$ denote the complete $r$-graph on $n$ vertices.

Let $G$ and $F$ be $r$-graphs. An $F$-decomposition of $G$ is a collection $F$ of copies of $F$ in $G$ such that every edge of $G$ is contained in exactly one of these copies. (Throughout the paper, we always assume that $F$ is non-empty without mentioning this explicitly.) More generally, an $(F, \lambda)$-design of $G$ is a collection $F$ of distinct copies of $F$ in $G$ such that every edge of $G$ is contained in exactly $\lambda$ of these copies. As discussed in Section 1.2, such a design can only exist if $G$ satisfies certain divisibility conditions (e.g. if $F$ is a graph triangle and $\lambda = 1$, then $G$ must have even vertex degrees and the number of edges must be a multiple of three). If $F$ and $G$ are complete, such designs are also referred to as block designs. More precisely, an $(n, f, r, \lambda)$-block design (or $r$-$(n, f, \lambda)$-block design) is a set $X$ of $f$-subsets of some $n$-set $V$, such that every $r$-subset of $V$ belongs to exactly $\lambda$ elements of $X$. The $f$-subsets are often called ‘blocks’. An $(n, f, r, 1)$-block design is also called an $(n, f, r)$-Steiner system. Note that an $(n, f, r, \lambda)$-block design is a $(K_{f}^{(r)}, \lambda)$-design of $K_{n}^{(r)}$.

The question of the existence of such designs goes back to the 19th century. For instance, Steiner asked in 1853 for which parameters Steiner systems exist. The first general result was due

---

1This paper combines the two manuscripts arXiv:1611.06827v1 and arXiv:1706.01800.
to Kirkman [26], who proved the existence of Steiner triple systems (i.e. triangle decompositions of complete graphs) under the appropriate divisibility conditions. In fact, the existence conjecture postulated that for any given parameters \( f, r, \lambda \), the necessary divisibility conditions are sufficient for the existence of an \( (n, f, r, \lambda) \)-block design for all sufficiently large \( n \). In a ground-breaking series of papers which transformed the area, Wilson [47, 48, 49, 50] solved the existence problem in the graph setting (i.e. when \( r = 2 \)) by showing that for any graph \( F \) the trivially necessary divisibility conditions imply the existence of \((F, \lambda)\)-designs in \( K_n^{(2)} \) for sufficiently large \( n \).

For \( r \geq 3 \), much less was known until very recently. Answering a question of Erdős and Hanani [16], Rödl [40] was able to give an approximate solution to the existence conjecture by constructing near optimal packings of edge-disjoint copies of \( K_f^{(r)} \) in \( K_n^{(r)} \), i.e. constructing a collection of edge-disjoint copies of \( K_f^{(r)} \) which cover almost all the edges of \( K_n^{(r)} \). (For this, he introduced his now famous Rödl nibble method, which has since had a major impact in many areas.) His bounds were subsequently improved by increasingly sophisticated randomised techniques (see e.g. [1, 46]). Ferber, Hod, Krivelevich and Sudakov [17] recently observed that this method can be used to obtain an ‘almost’ Steiner system in the sense that every \( r \)-set is covered by either one or two \( f \)-sets.

Teirlinck [45] was the first to prove the existence of infinitely many non-trivial \((n, f, r, \lambda)\)-block designs for arbitrary \( r \geq 6 \), via an ingenious recursive construction based on the symmetric group (this however requires \( f = r + 1 \) and \( \lambda \) large compared to \( f \)). Kuperberg, Lovett and Peled [31] proved a ‘localised central limit theorem’ for rigid combinatorial structures, which implies the existence of designs for arbitrary \( f \) and \( r \), but again for large \( \lambda \). There are many constructions resulting in sporadic and infinite families of designs (see e.g. the handbook [13]). However, the set of parameters they cover is very restricted. In particular, even the existence of infinitely many Steiner systems with \( r \geq 4 \) was open until recently.

In a recent breakthrough, Keevash [23] proved the existence of \((n, f, r, \lambda)\)-block designs for arbitrary (but fixed) \( r, f \) and \( \lambda \), provided \( n \) is sufficiently large and satisfies the trivially necessary divisibility conditions. In particular, his result implies the existence of Steiner systems for any admissible range of parameters as long as \( n \) is sufficiently large compared to \( f \). The approach in [23] involved randomised algebraic constructions and yielded a far-reaching generalisation to block designs in quasirandom \( r \)-graphs.

Here we develop a non-algebraic approach based on iterative absorption, which additionally yields resilience versions and the existence of block designs in hypergraphs of large minimum degree. Moreover, we are able to go beyond the setting of block designs and show that \( F \)-designs also exist for arbitrary \( r \)-graphs \( F \) whenever the necessary divisibility conditions are satisfied.

### 1.2. \( F \)-designs in quasirandom hypergraphs

We now describe the degree conditions which are trivially necessary for the existence of an \( F \)-design in an \( r \)-graph \( G \). For a set \( S \subseteq V(G) \) with \( 0 \leq |S| \leq r \), the \((r - |S|)\)-graph \( G(S) \) has vertex set \( V(G) \setminus S \) and contains all \((r - |S|)\)-subsets of \( V(G) \setminus S \) that together with \( S \) form an edge in \( G \). \( G(S) \) is often called the link graph of \( S \). Let \( \delta(G) \) and \( \Delta(G) \) denote the minimum and maximum \((r - 1)\)-degree of an \( r \)-graph \( G \), respectively, that is, the minimum/maximum value of \(|G(S)|\) over all \( S \subseteq V(G) \) of size \( r - 1 \). For a (non-empty) \( r \)-graph \( F \), we define the divisibility vector of \( F \) as \( \text{Deg}(F) := (d_0, \ldots, d_{r-1}) \in \mathbb{N}^r \), where \( d_i := \gcd\{|F(S)| : S \in \binom{V(F)}{i}\} \), and we set \( \text{Deg}(F)_i := d_i \) for \( 0 \leq i \leq r - 1 \). Note that \( d_0 = |F| \). So if \( F \) is the Fano plane, we have \( \text{Deg}(F) = (7, 3, 1) \).

Given \( r \)-graphs \( F \) and \( G \), \( G \) is called \((F, \lambda)\)-divisible if \( \text{Deg}(F)_i | \lambda |G(S)| \) for all \( 0 \leq i \leq r - 1 \) and all \( S \in \binom{V(G)}{i} \). Note that \( G \) must be \((F, \lambda)\)-divisible in order to admit an \((F, \lambda)\)-design. Indeed, suppose that \( F \) is an \((F, \lambda)\)-design of \( G \), and consider \( 0 \leq i \leq r - 1 \) and any \( S \in \binom{V(G)}{i} \). Since every edge of \( G \) is covered exactly \( \lambda \) times, we have \( \sum_{F' \in \mathcal{F}} |F'(S)| = \lambda |G(S)| \). Since \( \text{Deg}(F)_i | |F'(S)| \) for all \( F' \in \mathcal{F} \) by definition, we have \( \text{Deg}(F)_i | \lambda |G(S)| \). For simplicity, we say that \( G \) is \( F \)-divisible if \( G \) is \((F, 1)\)-divisible. Thus \( F \)-divisibility of \( G \) is necessary for the existence of an \( F \)-decomposition of \( G \).
As a special case, the following result implies that \((F, \lambda)\)-divisibility is sufficient to guarantee the existence of an \((F, \lambda)\)-design when \(G\) is complete and \(\lambda\) is not too large. This answers a question asked e.g. by Keevash [23].

In fact, rather than requiring \(G\) to be complete, it suffices that \(G\) is quasirandom in the following sense. An \(r\)-graph \(G\) on \(n\) vertices is called \((c, h, p)\)-\(\gamma\)-typical if for any set \(A\) of \((r - 1)\)-subsets of \(V(G)\) with \(|A| \leq h\) we have \(|\bigcap_{S \in A} G(S)| = (1 \pm c)p^{|A|}n\). Note that this is what one would expect in a random \(r\)-graph with edge probability \(p\).

**Theorem 1.1 (\(F\)-designs in typical hypergraphs).** For all \(f, r \in \mathbb{N}\) with \(f > r\) and all \(c, p \in (0, 1]\) with

\[
c \leq 0.9(p/2)^h/(q^r 4^q), \text{ where } q := 2f \cdot f! \text{ and } h := 2^{f} \binom{q + r}{r},
\]

there exist \(n_0, C \in \mathbb{N}\) such that the following holds for all \(n \geq n_0\). Let \(F\) be any \(r\)-graph on \(f\) vertices and let \(\lambda \in \mathbb{N}\) with \(\lambda \leq \gamma n\). Suppose that \(G\) is a \((c, h, p)\)-\(\gamma\)-typical \(r\)-graph on \(n\) vertices. Then \(G\) has an \((F, \lambda)\)-design if it is \((F, \lambda)\)-divisible.

The main result in [23] is also stated in the setting of typical \(r\)-graphs, but additionally requires that \(c \ll 1/h \ll p, 1/f\) and that \(\lambda = O(1)\) and \(F\) is complete.

Previous results in the case when \(r \geq 3\) and \(F\) is not complete are very sporadic – for instance Hanani [21] settled the problem if \(F\) is an octahedron (viewed as a 3-uniform hypergraph) and \(G\) is complete.

In Section 9, we will deduce Theorem 1.1 from a more general result on \(F\)-decompositions in supercomplexes \(G\) (Theorem 4.7). The condition of \(G\) being a supercomplex is considerably less restrictive than typicality. Moreover, the \(F\)-designs we obtain will have the additional property that \(|V(F') \cap V(F'')| \leq r\) for all distinct \(F', F''\) which are included in the design. It is easy to see that with this additional property the bound on \(\lambda\) in Theorem 1.1 is best possible up to the value of \(\gamma\).

We can also deduce the following result which yields ‘near-optimal’ \(F\)-packings in typical \(r\)-graphs which are not divisible. (An \(F\)-packing in \(G\) is a collection of edge-disjoint copies of \(F\) in \(G\).)

**Theorem 1.2.** For all \(f, r \in \mathbb{N}\) with \(f > r\) and all \(c, p \in (0, 1]\) with

\[
c \leq 0.9 p^h/(q^r 4^q), \text{ where } q := 2f \cdot f! \text{ and } h := 2^{f} \binom{q + r}{r},
\]

there exist \(n_0, C \in \mathbb{N}\) such that the following holds for all \(n \geq n_0\). Let \(F\) be any \(r\)-graph on \(f\) vertices. Suppose that \(G\) is a \((c, h, p)\)-\(\gamma\)-typical \(r\)-graph on \(n\) vertices. Then \(G\) has an \(F\)-packing \(F\) such that the leftover \(L\) consisting of all uncovered edges satisfies \(\Delta(L) \leq C\).

1.3. \(F\)-designs in hypergraphs of large minimum degree. Once the existence question is settled, a next natural step is to seek \(F\)-designs and \(F\)-decompositions in \(r\)-graphs of large minimum degree. Our next result gives a bound on the minimum degree which ensures an \(F\)-decomposition for ‘weakly regular’ \(r\)-graphs \(F\). These are defined as follows.

**Definition 1.3 (weakly regular).** Let \(F\) be an \(r\)-graph. We say that \(F\) is weakly \((s_0, \ldots, s_{r-1})\)-regular if for all \(0 \leq i \leq r - 1\) and all \(S \in \binom{V(F)}{i}\), we have \(|F(S)| \in \{0, s_i\}\). We simply say that \(F\) is weakly regular if it is weakly \((s_0, \ldots, s_{r-1})\)-regular for suitable \(s_i\)’s.

So for example, cliques, the Fano plane and the octahedron are all weakly regular but a 3-uniform tight or loose cycle is not.

**Theorem 1.4 (\(F\)-decompositions in hypergraphs of large minimum degree).** Let \(F\) be a weakly regular \(r\)-graph on \(f\) vertices. Let

\[
c_F^\circ := \frac{r!}{3 \cdot 14^f f^{2r}}.
\]

There exists an \(n_0 \in \mathbb{N}\) such that the following holds for all \(n \geq n_0\). Suppose that \(G\) is an \(r\)-graph on \(n\) vertices with \(\delta(G) \geq (1 - c_F^\circ) n\). Then \(G\) has an \(F\)-decomposition if it is \(F\)-divisible.
We will actually deduce Theorem 1.4 from a ‘resilience version’ (Theorem 9.3). An analogous (but significantly worse) constant \( c_F^p \) for \( r \)-graphs \( F \) which are not weakly regular immediately follows from the case \( p = 1 \) of Theorem 1.1.

Note that Theorem 1.4 implies that whenever \( X \) is a partial \((n, f, r)\)-Steiner system (i.e. a set of edge-disjoint \( K^{(r)}_f \) on \( n \) vertices) and \( n^* \geq \max\{n_0, n/c^{(r)}_F\} \) satisfies the necessary divisibility conditions, then \( X \) can be extended to an \((n^*, f, r)\)-Steiner system. For the case of Steiner triple systems (i.e. \( f = 3 \) and \( r = 2 \)), Bryant and Horsley [11] showed that one can take \( n^* = 2n + 1 \), which proved a conjecture of Lindner.

Theorem 1.4 leads to the concept of the ‘decomposition threshold’ \( \delta_F \) of a given \( r \)-graph \( F \).

**Definition 1.5** (Decomposition threshold). Given an \( r \)-graph \( F \), let \( \delta_F \) be the infimum of all \( \delta \in [0,1] \) with the following property: There exists \( n_0 \in \mathbb{N} \) such that for all \( n \geq n_0 \), every \( F \)-divisible \( r \)-graph \( G \) on \( n \) vertices with \( \delta(G) \geq (1 - b_r \log f/r^n)n \) such that \( G_n \) does not contain a single copy of \( K_f^{(r)} \), where \( b_r > 0 \) only depends on \( r \). This can be seen by adapting a construction from [28] as follows. Without loss of generality, we may assume that \( 1/f < 1/r \). By a result of [43], for every \( r \geq 2 \), there exists a constant \( b_r \) such that for any large enough \( f \), there exists a partial \((N, r, r - 1)\)-Steiner system \( S_N \) with independence number \( \alpha(S_N) < f/(r - 1) \) and \( N/N \leq b_r \log f/f^{r - 1} \). This partial Steiner system can be ‘blown up’ (cf. [28]) to obtain arbitrarily large \( r \)-graphs \( H_n \) on \( n \) vertices with \( \alpha(H_n) < f \) and \( \Delta(H_n) \leq n/N \leq b_r \log f/f^{r - 1} \). Then the complement \( G_n \) of \( H_n \) is \( K_f^{(r)} \)-free and satisfies \( \delta(G_n) \geq (1 - b_r \log f/r^n)n \).

Previously, the only explicit result for the hypergraph case \( r \geq 3 \) was due to Yuster [51], who showed that if \( T \) is a linear \( r \)-uniform hypertree, then every \( T \)-divisible \( r \)-graph \( G \) on \( n \) vertices with minimum vertex degree at least \((1/(2^{r - 1}) + o(1))(\binom{n}{r})\) has a \( T \)-decomposition. This is asymptotically best possible for nontrivial \( T \). Moreover, the result implies that \( \delta_T \leq 1/2^{r - 1} \).

For the graph case \( r = 2 \), much more is known about the decomposition threshold: the results in [7, 19] establish a close connection between \( \delta_F \) and the fractional decomposition threshold \( \delta_F^* \) (which is defined as in Definition 1.5, but with an \( F \)-decomposition replaced by a fractional \( F \)-decomposition). In particular, the results in [7, 19] imply that \( \delta_F \leq \max\{\delta_F^*, 1 - 1/(\chi(F) + 1)\} \) and that \( \delta_F = \delta_F^* \) if \( F \) is a complete graph.

Together with recent results on the fractional decomposition threshold for cliques in [6, 14], this gives the best current bounds on \( \delta_F \) for general \( F \). It would be very interesting to establish a similar connection in the hypergraph case.

Also, for bipartite graphs the decomposition threshold was completely determined in [19]. It would be interesting to see if this can be generalised to \( r \)-partite \( r \)-graphs. On the other hand, even the decomposition threshold of a graph triangle is still unknown (a beautiful conjecture of Nash-Williams [36] would imply that the value is 3/4).

### 1.4 Varying block sizes

We now briefly consider a more general notion of block designs, where more than just one block order is admissible. Given \( n, r, \lambda \in \mathbb{N} \) as before and \( A \subseteq \mathbb{N} \), we say that \( X \) is an \((n, A, r, \lambda)\)-block design if \( X \) consists of subsets of an \( n \)-set \( V \) such that \(|x| \in A\) for every \( x \in X \) and such that every \( r \)-subset of \( V \) is contained in precisely \( \lambda \) elements of \( X \). Similarly, given an \( r \)-graph \( G \) and a family of \( r \)-graphs \( \mathcal{K} \), we say that \( \mathcal{F} \) is a \( \mathcal{K} \)-decomposition of \( G \) if every edge of \( G \) lies in precisely one \( F \in \mathcal{F} \) and if \( F \in \mathcal{K} \) for each \( F \in \mathcal{F} \). For instance, a \( \{K^{(r)}_a : a \in A\} \)-decomposition of \( K^{(r)}_f \) is equivalent to an \((n, A, r, 1)\)-block design. We say that \( G \) is \( \mathcal{K} \)-divisible if \( \gcd\{\deg(F)_i : F \in \mathcal{K}\} = \deg(G)_i \) for all \( 0 \leq i \leq r - 1 \). Clearly, \( \mathcal{K} \)-divisibility is a necessary condition for the existence of a \( \mathcal{K} \)-decomposition. Theorem 1.1 easily implies the following result (see Section 9).

**Theorem 1.6** (Designs with varying block sizes). For all \( f, r \in \mathbb{N} \) and \( p \in (0, 1] \) there exist \( c > 0 \), \( h \in \mathbb{N} \) and \( n_0 \in \mathbb{N} \) such that the following holds for all \( n \geq n_0 \). Let \( \mathcal{K} \) be a family of \( r \)-graphs of
order at most \( f \) each. Suppose that \( G \) is a \((c, h, p)\)-typical \( r \)-graph on \( n \) vertices. Then \( G \) has a \( K \)-decomposition if it is \( K \)-divisible.

As a very special case, Theorem 1.6 resolves a conjecture of Archdeacon on self-dual embeddings of random graphs in orientable surfaces: as proved in [3], a graph has such an embedding if it has a \( \{K_4, K_5\} \)-decomposition. (In this paragraph, we write \( K_n \) for \( K_n^{(2)} \).) Note that every graph with an even number of edges is \( \{K_4, K_5\} \)-divisible. Suppose \( G \) is a \((c, h, p)\)-typical graph on \( n \) vertices with an even number of edges and \( 1/n \leq c < 1/h \leq p \) (which almost surely holds for the binomial random graph \( G_{n, p} \) if we remove at most one edge). Then we can apply Theorem 1.6 to obtain a \( \{K_4, K_5\} \)-decomposition of \( G \). It was also shown in [3] that a graph has a self-dual embedding in a non-orientable surface if it has a \( \{K_6 : a \geq 4\} \)-decomposition. Since every graph is \( \{K_4, K_5, K_6\} \)-divisible, say, Theorem 1.6 implies that almost every graph has a \( \{K_4, K_5, K_6\} \)-decomposition and thus a self-dual embedding.

1.5. Matchings and further results. As another illustration, we now state a consequence of our main result which concerns perfect matchings in hypergraphs that satisfy certain uniformity conditions on their edge distribution. Note that the conditions are much weaker than any standard pseudorandomness notion.

**Theorem 1.7.** For all \( f \geq 2 \) and \( \xi > 0 \) there exists \( n_0 \in \mathbb{N} \) such that the following holds whenever \( n \geq n_0 \) and \( f \mid n \). Let \( G \) be a \( f \)-graph on \( n \) vertices which satisfies the following properties:

- for some \( d \geq \xi \), \( |G(v)| = (d \pm 0.01\xi)n^{f-1} \) for all \( v \in V(G) \);
- every vertex is contained in at least \( \xi n^f \) copies of \( K_{f+1}^{(f)} \);
- \( |G(v) \cap G(w)| \geq \xi n^{f-1} \) for all \( v, w \in V(G) \).

Then \( G \) has at least \( 0.01\xi n^{f-1} \) edge-disjoint perfect matchings.

Note that for \( G = K_n^{(f)} \), this is strengthened by Baranyai’s theorem [4], which states that \( K_n^{(f)} \) has a decomposition into \( \binom{n-f}{f-1} \) edge-disjoint perfect matchings. More generally, the interplay between designs and the existence of (almost) perfect matchings in hypergraphs has resulted in major developments over the past decades, e.g. via the Rödl nibble. For more recent progress on results concerning perfect matchings in hypergraphs and related topics, see e.g. the surveys [41, 52, 53].

We discuss further applications of our main result in Section 4, e.g. to partite graphs (see Example 4.11) and to \((n, f, r, \lambda)\)-block designs where we allow any \( \lambda \leq n^{f-r}/(11 \cdot 7^f f!) \), say (under more restrictive divisibility conditions, see Corollary 4.14).

1.6. Counting. An approximate \( F \)-decomposition of \( K_n^{(r)} \) is a set of edge-disjoint copies of \( F \) in \( K_n^{(r)} \) which together cover almost all edges of \( K_n^{(r)} \). Given good bounds on the number of approximate \( F \)-decompositions of \( K_n^{(r)} \) whose set of leftover edges forms a typical \( r \)-graph, one can apply Theorem 1.1 to obtain corresponding bounds on the number of \( F \)-decompositions in \( K_n^{(r)} \) (see [23, 24] for the clique case). Such lower bounds on the number of approximate \( F \)-decompositions can be achieved by considering either a random greedy \( F \)-removal process or an associated \( F \)-nibble removal process. Linial and Luria [33] developed an entropy-based approach which they used to obtain good upper bounds e.g. on the number of Steiner triple systems. These developments also make it possible to systematically study random designs (see Kwan [32] for an investigation of random Steiner triple systems).

1.7. Outline of the paper. As mentioned earlier, our main result (Theorem 4.7) actually concerns \( F \)-decompositions in so-called supercomplexes. We will define supercomplexes in Section 4 and derive Theorems 1.1, 1.2, 1.4, 1.6 and 1.7 in Section 9. The definition of a supercomplex \( G \) involves mainly the distribution of cliques of size \( f \) in \( G \) (where \( f = |V(F)| \)). The notion is weaker than usual notions of quasirandomness. This has two main advantages: firstly, our proof is by induction on \( r \), and working with this weaker notion is essential to make the induction proof work. Secondly, this allows us to deduce Theorems 1.1, 1.2, 1.4, 1.6 and 1.7 from a single statement.
However, Theorem 4.7 applies only to $F$-decompositions of a supercomplex $G$ for weakly regular $r$-graphs $F$ (which allows us to deduce Theorem 1.4 but not Theorem 1.1).

To deal with this, in Section 9 we first provide an explicit construction which shows that every $r$-graph $F$ can be ‘perfectly’ packed into a suitable weakly regular $r$-graph $F^*$. In particular, $F^*$ has an $F$-decomposition. The idea is then to apply Theorem 4.7 to find an $F^*$-decomposition in $G$. Unfortunately, $G$ may not be $F^*$-divisible. To overcome this, in Section 11 we show that we can remove a small set of copies of $F$ from $G$ to achieve that the leftover $G'$ of $G$ is now $F^*$-divisible (see Lemma 9.4 for the statement). This now implies Theorem 1.1 for $F$-decompositions, i.e. for $\lambda = 1$. However, by repeatedly applying Theorem 4.7 in a suitable way, we can actually allow $\lambda$ to be as large as required in Theorem 1.1.

It thus remains to prove Theorem 4.7 itself. We achieve this via an approach based on ‘iterative absorption’. We give a sketch of the argument in Section 3.

As a byproduct of the construction of the weakly regular $r$-graph $F^*$ outlined above, we prove the existence of resolvable clique decompositions in complete partite $r$-graphs $G$ (see Theorem 9.1). The construction is explicit and exploits the property that all square submatrices of so-called Cauchy matrices over finite fields are invertible. We believe this construction to be of independent interest. A natural question leading on from the current work would be to obtain such resolvable decompositions also in the general (non-partite) case. For decompositions of $K_n^{(2)}$ into $K_j^{(2)}$, this is due to Ray-Chaudhuri and Wilson [39]. For related results see [15, 34].

2. Notation

2.1. Basic terminology. We let $[n]$ denote the set $\{1, \ldots, n\}$, where $[0] := \emptyset$. Moreover, let $[n]_0 := [n] \cup \{0\}$ and $\mathbb{N}_0 := \mathbb{N} \cup \{0\}$. As usual, $\binom{n}{i}$ denotes the binomial coefficient, where we set $\binom{n}{i} := 0$ if $i > n$ or $i < 0$. Moreover, given a set $X$ and $i \in \mathbb{N}_0$, we write $\binom{X}{i}$ for the collection of all $i$-subsets of $X$. Hence, $\binom{X}{i} = \emptyset$ if $i > |X|$. If $F$ is a collection of sets, we define $\bigcup F := \bigcup_{x \in F} x$.

We write $A \cup B$ for the union of $A$ and $B$ if we want to emphasise that $A$ and $B$ are disjoint.

We write $X \sim B(n,p)$ if $X$ has binomial distribution with parameters $n, p$, and we write $\text{bin}(n, p, i) := \binom{n}{i} p^i (1-p)^{n-i}$. So by the above convention, $\text{bin}(n, p, i) = 0$ if $i > n$ or $i < 0$.

We say that an event holds with high probability (whp) if the probability that it holds tends to 1 as $n \to \infty$ (where $n$ usually denotes the number of vertices).

We write $x \ll y$ to mean that for any $y \in (0, 1]$ there exists an $x_0 \in (0, 1)$ such that for all $x \leq x_0$ the subsequent statement holds. Hierarchies with more constants are defined in a similar way and are to be read from the right to the left. We will always assume that the constants in our hierarchies are reals in $(0,1]$. Moreover, if $1/x$ appears in a hierarchy, this implicitly means that $x$ is a natural number. More precisely, $1/x \ll y$ means that for any $y \in (0, 1]$ there exists an $x_0 \in \mathbb{N}$ such that for all $x \in \mathbb{N}$ with $x \geq x_0$ the subsequent statement holds.

We write $a = b \pm c$ if $b - c \leq a \leq b + c$. Equations containing $\pm$ are always to be interpreted from left to right, e.g. $b_1 \pm c_1 = b_2 \pm c_2$ means that $b_1 - c_1 \geq b_2 - c_2$ and $b_1 + c_1 \leq b_2 + c_2$. We will often use the fact that for all $0 < x < 1$ and $n \in \mathbb{N}$ we have $(1 \pm x)^n = 1 \pm 2^n x$.

When dealing with multisets, we treat multiple appearances of the same element as distinct elements. In particular, two subsets $A, B$ of a multiset can be disjoint even if they both contain a copy of the same element, and if $A$ and $B$ are disjoint, then the multiplicity of an element in the union $A \cup B$ is obtained by adding the multiplicities of this element in $A$ and $B$ (rather than just taking the maximum).

2.2. Hypergraphs and complexes. Let $G$ be an $r$-graph. Note that $G(\emptyset) = G$. For a set $S \subseteq V(G)$ with $|S| \leq r$ and $L \subseteq G(S)$, let $S \uplus L := \{S \cup e : e \in L\}$. Clearly, there is a natural bijection between $L$ and $S \uplus L$.

For $i \in [r - 1]_0$, we define $\delta_i(G)$ and $\Delta_i(G)$ as the minimum and maximum value of $|G(S)|$ over all $i$-subsets $S$ of $V(G)$, respectively. As before, we let $\delta(G) := \delta_{r-1}(G)$ and $\Delta(G) := \Delta_{r-1}(G)$. Note that $\delta_0(G) = \Delta_0(G) = |G(\emptyset)| = |G|$.

For two $r$-graphs $G$ and $G'$, we let $G - G'$ denote the $r$-graph obtained from $G$ by deleting all edges of $G'$, and let $G \triangle G' := (G - G') \cup (G' - G)$. We write $G_1 + G_2$ to mean the vertex-disjoint union of $G_1$ and $G_2$, and $t \cdot G$ to mean the vertex-disjoint union of $t$ copies of $G$. 

Let \( F \) and \( G \) be \( r \)-graphs. An \( F \)-packing in \( G \) is a set \( \mathcal{F} \) of edge-disjoint copies of \( F \) in \( G \). We let \( \mathcal{F}^{(r)} \) denote the \( r \)-graph consisting of all covered edges of \( G \), i.e., \( \mathcal{F}^{(r)} = \bigcup_{F \in \mathcal{F}} F' \).

A multi-\( r \)-graph \( G \) consists of a set of vertices \( V(G) \) and a multiset of edges \( E(G) \), where each \( e \in E(G) \) is a subset of \( V(G) \) of size \( r \). We will often identify a multi-\( r \)-graph with its edge set. For \( S \subseteq V(G) \), let \( |G(S)| \) denote the number of edges of \( G \) that contain \( S \) (counted with multiplicities). If \( |S| = r \), then \( |G(S)| \) is called the multiplicity of \( S \) in \( G \). We say that \( G \) is \( F \)-divisible if \( |G(S)| \) divides \( |G(S)| \) for all \( S \subseteq V(G) \) with \( |S| \leq r - 1 \). An \( F \)-decomposition of \( G \) is a collection \( \mathcal{F} \) of copies of \( F \) in \( G \) such that every edge \( e \in G \) is covered precisely once. (Thus if \( S \subseteq V(G) \) has size \( r \), then there are precisely \( |G(S)| \) copies of \( F \) in \( \mathcal{F} \) in which \( S \) forms an edge.)

**Definition 2.1.** A complex \( G \) is a hypergraph which is closed under inclusion, that is, whenever \( e' \subseteq e \in G \) we have \( e' \in G \). If \( G \) is a complex and \( i \in \mathbb{N}_0 \), we write \( G^{(i)} \) for the \( i \)-graph on \( V(G) \) consisting of all \( e \subseteq G \) with \( |e| = i \). We say that a complex is empty if \( \emptyset \notin G^{(0)} \), that is, if \( G \) does not contain any edges.

Suppose \( G \) is a complex and \( e \subseteq V(G) \). Define \( G(e) \) as the complex on vertex set \( V(G) \setminus e \) containing all sets \( e' \subseteq V(G) \setminus e \) such that \( e \cup e' \in G \). Clearly, if \( e \notin G \), then \( G(e) \) is empty. Observe that if \( |e| = i \) and \( r \geq i \), then \( G^{(r)}(e) = G(e)^{(r-i)} \). We say that \( G' \) is a subcomplex of \( G \) if \( G' \) is a complex and a subhypergraph of \( G \).

For a set \( U \), define \( G[U] \) as the complex on \( U \cap V(G) \) containing all \( e \in G \) with \( e \subseteq U \). Moreover, for an \( r \)-graph \( H \), let \( G[H] \) be the complex on \( V(G) \) with edge set
\[
G[H] := \{ e \in G : \binom{e}{r} \subseteq H \},
\]
and define \( G - H := G[G^{(r)} - H] \). So for \( i \in [r-1] \), \( G[H]^{(i)} = G^{(i)} \) (since \( \binom{r}{i} = \emptyset \subseteq H \) when \( |e| < r \)). For \( i > r \), we might have \( G[H]^{(i)} \nsubseteq G^{(i)} \). Moreover, if \( H \subseteq G^{(r)} \), then \( G[H]^{(r)} = H \). Note that for an \( r_1 \)-graph \( H_1 \) and an \( r_2 \)-graph \( H_2 \), we have \( (G[H_1])[H_2] = (G[H_2])[H_1] \). Also, \( G - H_1 \times H_2 = (G - H_2) - H_1 \), so we may write this as \( G - H_1 - H_2 \).

If \( G_1 \) and \( G_2 \) are complexes, we define \( G_1 \cap G_2 \) as the complex on vertex set \( V(G_1) \cap V(G_2) \) containing all sets \( e \) with \( e \in G_1 \) and \( e \in G_2 \). We say that \( G_1 \) and \( G_2 \) are \( i \)-disjoint if \( G_1^{(i)} \cap G_2^{(i)} \) is empty.

For any hypergraph \( H \), let \( H^{\leq} \) be the complex on \( V(H) \) generated by \( H \), that is,
\[
H^{\leq} := \{ e \subseteq V(H) : \exists e' \in H \text{ such that } e \subseteq e' \}.
\]

For an \( r \)-graph \( H \), we let \( H^{\leftrightarrow} \) denote the complex on \( V(H) \) that is induced by \( H \), that is,
\[
H^{\leftrightarrow} := \{ e \subseteq V(H) : \binom{e}{r} \subseteq H \}.
\]
Note that \( H^{\leftrightarrow}(r) = H \) and for each \( i \in [r-1]_0 \), \( H^{\leftrightarrow}(i) \) is the complete \( i \)-graph on \( V(H) \). We let \( K_n \) denote the the complete complex on \( n \) vertices.

### 3. Outline of the methods

Rather than an algebraic approach as in [23], we pursue a combinatorial approach based on ‘iterative absorption’. In particular, we do not make use of any nontrivial algebraic techniques and results, but rely only on probabilistic tools.

#### 3.1. Iterative absorption

Suppose for simplicity that we aim to find a \( K_f^{(r)} \)-decomposition of a suitable \( r \)-graph \( G \). The Rödl nibble (see e.g. [1, 37, 40, 46]) allows us to obtain an approximate \( K_f^{(r)} \)-decomposition of \( G \), i.e. a set of edge-disjoint copies of \( K_f^{(r)} \) covering almost all edges of \( G \). However, one has little control over the resulting uncovered leftover set of edges. The basic aim of an absorbing approach is to overcome this issue by removing an absorbing structure \( A \) right at the beginning and then applying the Rödl nibble to \( G - A \), to obtain an approximate decomposition with a very small uncovered remainder \( R \). Ideally, \( A \) was chosen in such a way that \( A \cup R \) has a \( K_f^{(r)} \)-decomposition.
Such an approach was introduced systematically by Rödl, Ruciński and Szemerédi [42] in order to find spanning structures in graphs and hypergraphs (but actually goes back further than this, see e.g. Krivelevich [29]). In the context of decompositions, the first results based on an absorbing approach were obtained in [27, 30]. In contrast to the construction of spanning subgraphs, the decomposition setting gives rise to the additional challenge that the number of and possible shape of uncovered remainder graphs \( R \) is comparatively large. So in general it is much less clear how to construct a structure \( A \) which can deal with all such possibilities for \( R \) (to appreciate this issue, note that \( V(R) = V(G) \) in this scenario).

The method developed in [27, 30] consisted of an iterative approach: each iteration consists of an approximate decomposition of the previous leftover, together with a partial absorption (or ‘cleaning’) step, which further restricts the structure of the current leftover. In our context, we carry out this iteration by considering a ‘vortex’. Such a vortex is a nested sequence \( V(G) = U_0 \supseteq U_1 \supseteq \cdots \supseteq U_\ell \), where \( |U_i|/|U_{i+1}| \) and \( |U_\ell| \) are large but bounded. Crucially, after the \( i \)-th iteration, all \( r \)-edges belonging to the current leftover \( R_i \) will be induced by \( U_i \). In the \((i+1)\)th iteration, we make use of a suitable \( r \)-graph \( H_i \) on \( U_i \) which we set aside at the start. We first apply the Rödl nibble to \( R_i \) to obtain a sparse remainder \( R_i' \). We then apply what we refer to as the ‘Cover down lemma’ to find a \( K_f^{(r)} \)-packing \( K_i \) of \( H_i \cup R_i' \) so that the remainder \( R_{i+1} \) consists entirely of \( r \)-edges induced by \( U_{i+1} \) (see Lemma 7.7). Ultimately, we arrive at a leftover \( R_\ell \) induced by \( U_\ell \).

Since \( |U_\ell| \) is bounded, this means there are only a bounded number of possibilities \( S_1, \ldots, S_b \) for \( R_\ell \). This gives a natural approach to the construction of an absorber \( A \) for \( R_\ell \): it suffices to construct an ‘exclusive’ absorber \( A_i \) for each \( S_i \) (in the sense that \( A_i \) can absorb \( S_i \) but nothing else). More precisely, we aim to construct edge-disjoint \( r \)-graphs \( A_1, \ldots, A_b \) so that both \( A_i \) and \( A_1 \cup \cdots \cup A_b \) have a \( K_f^{(r)} \)-decomposition, and then let \( A := A_1 \cup \cdots \cup A_b \). Then \( A \cup R_\ell \) must also have a \( K_f^{(r)} \)-decomposition.

Iterative absorption based on vortices was introduced in [19], building on a related (but more complicated approach) in [7]. Developing the above approach in the setting of hypergraph decompositions gives rise to two main challenges: constructing the ‘exclusive’ absorbers and proving the Cover down lemma, which we discuss in the next two subsections, respectively.

One difficulty with the iteration process is that after finishing one iteration, the error terms are too large to carry out the next one. Fortunately, we are able to ‘boost’ our regularity parameters before each iteration by excluding suitable \( f \)-cliques from future consideration (see Lemma 6.3). For this, we adopt gadgets introduced in [6]. Moreover, the ‘Boost lemma’ enables us to obtain explicit bounds e.g. in the minimum degree version (Theorem 1.4).

3.2. The Cover down lemma. As indicated above, the goal here is as follows: Given an \( r \)-graph \( G \) and vertex sets \( U_{i+1} \subseteq U_i \) in \( G \), we need to construct \( H^* \) in \( G[U_i^{(r)}] \) so that for any sparse leftover \( R \) on \( U_i \), we can find a \( K_f^{(r)} \)-packing in \( H^* \cup R \) such that any leftover edges lie in \( U_{i+1} \). (In addition, we need to ensure that the distribution of the leftover edges within \( U_{i+1} \) is sufficiently well-behaved so that we can continue with the next iteration, but we do not discuss this aspect here.)

We achieve this goal in several stages: given an edge \( e \in H^* \cup R \), we refer to the size of its intersection with \( U_{i+1} \) as its type. Initially, we cover all edges of type 0. This can be done using an appropriate greedy approach, i.e. for each edge \( e \) of type 0 in turn, we extend \( e \) to a copy of \( K_f^{(r)} \) using edges of \( H^* \). In the next stage, we cover all edges of type 1, then all edges of type 2 up to and including type \( r - 1 \). When covering a given set of edges of type \( j \), we will inductively assume that our main decomposition result holds for \( j \)-graphs (note that \( j < r \)). For example, consider the triangle case \( f = 3 \) and \( r = 2 \), and suppose \( j = 1 \). Then for each vertex \( v \in U_i \setminus U_{i+1} \), we will inductively find a perfect matching (which can be viewed as a \( K_2^{(1)} \)-decomposition) on the neighbours of \( v \) in \( U_{i+1} \). This yields a triangle packing which covers all (remaining) edges incident to \( v \) (note that these edges have type 1). The resulting proof of the Cover down lemma is given in Section 10 (which also includes a more detailed sketch of this part of the argument).
3.3. Transformers and absorbers. Recall that our remaining goal is to construct an exclusive absorber \( A_S \) for a given ‘leftover’ \( r \)-graph \( S \) of bounded size. In other words, both \( A_S \cup S \) as well as \( A_S \) need to have a \( K_f^{(r)} \)-decomposition. Clearly, we must (and can) assume that \( S \) is \( K_f^{(r)} \)-divisible.

Based on an idea introduced in [7], we will construct \( A_S \) as a concatenation of ‘transformers’: given \( S \), a transformer \( T_S \) can be viewed as transforming \( S \) into a new leftover \( L \) (which has the same number of edges and is still divisible). Formally, we require that \( S \cup T_S \) and \( T_S \cup L \) both have a \( K_f^{(r)} \)-decomposition (and will set aside \( T_S \) and \( L \) at the beginning of the proof).

Since transformers act transitively, the idea is to concatenate them in order to transform \( S \) into a vertex-disjoint union of \( K_f^{(r)} \), i.e. we gradually transform the given leftover \( S \) into a graph which is trivially decomposable.

Roughly speaking, we approach this by choosing \( L \) to be a suitable ‘canonical’ graph (i.e. \( L \) only depends on \( |S| \)). Let \( S' \) denote the vertex-disjoint union of copies of \( K_f^{(r)} \) such that \( |S| = |S'| \), and let \( T_{S'} \) be the corresponding transformer from \( S' \) into \( L \). Then it is easy to see that we could let \( A_S := T_S \cup L \cup T_{S'} \cup S' \). The construction of both the canonical graph \( L \) as well as that of the transformer \( T_S \) is based on an inductive approach, i.e. we assume that our main decomposition result holds for \( r' \)-graphs with \( 1 \leq r' < r \). The above construction is given in Section 8.

4. Decompositions of supercomplexes

4.1. Supercomplexes. We prove our main decomposition theorem for so-called ‘supercomplexes’. The crucial property appearing in the definition is that of ‘regularity’, which means that every \( r \)-set of a given complex \( G \) is contained in roughly the same number of \( f \)-sets (where \( f = |V(F)| \)). If we view \( G \) as a complex which is induced by some \( r \)-graph, this means that every edge lies in roughly the same number of cliques of size \( f \). It turns out that this set of conditions is appropriate even when \( F \) is not a clique.

A key advantage of the notion of a supercomplex is that the conditions are very flexible, which will enable us to ‘boost’ their parameters (see Lemma 4.4 below).

**Definition 4.1.** Let \( G \) be a complex on \( n \) vertices, \( f \in \mathbb{N} \) and \( r \in [f - 1]_0, 0 \leq \epsilon, d, \xi \leq 1 \). We say that \( G \) is

1. \( (\epsilon, d, f, r) \)-regular, if for all \( e \in G^{(r)} \) we have
   \[ |G(f)(e)| = (d \pm \epsilon)n^{f-r}; \]
2. \( (\xi, f, r) \)-dense, if for all \( e \in G^{(r)} \), we have
   \[ |G(f)(e)| \geq \xi n^{f-r}; \]
3. \( (\xi, f, r) \)-extendable, if \( G^{(r)} \) is empty or there exists a subset \( X \subseteq V(G) \) with \( |X| \geq \xi n \) such that for all \( e \in \binom{X}{r} \), there are at least \( \xi n^{f-r} (f - r) \)-sets \( Q \subseteq V(G) \setminus e \) such that \( (Q \cup e) \subseteq G^{(r)} \).

We say that \( G \) is a full \( (\epsilon, \xi, f, r) \)-complex if \( G \) is

- \( (\epsilon, d, f, r) \)-regular for some \( d \geq \xi \),
- \( (\xi, f + r, r) \)-dense,
- \( (\xi, f, r) \)-extendable.

We say that \( G \) is an \( (\epsilon, \xi, f, r) \)-complex if there exists an \( f \)-graph \( Y \) on \( V(G) \) such that \( G[Y] \) is a full \( (\epsilon, \xi, f, r) \)-complex. Note that \( G[Y]^{(r)} = G^{(r)} \) (recall that \( r < f \)).

The additional flexibility offered by considering \( (\epsilon, \xi, f, r) \)-complexes rather than full \( (\epsilon, \xi, f, r) \)-complexes is key to proving our minimum degree result (via the ‘boosting’ step discussed below). We also note that for the scope of this paper, it would be sufficient to define extendability more restrictively, by letting \( X := V(G) \). However, for future applications, it might turn out to be useful that we do not require \( X = V(G) \).
Fact 4.2. Note that $G$ is an $(\varepsilon, \xi, f, 0)$-complex if and only if $G$ is empty or $|G^{(f)}| \geq \xi n^f$. In particular, every $(\varepsilon, \xi, f, 0)$-complex is a $(0, \xi, f, 0)$-complex.

Definition 4.3. (supercomplex) Let $G$ be a complex. We say that $G$ is an $(\varepsilon, \xi, f, r)$-supercomplex if for every $i \in [r]_0$ and every set $B \subseteq G^{(i)}$ with $1 \leq |B| \leq 2^i$, we have that $\cap_{b \in B} G(b)$ is an $(\varepsilon, \xi, f - i, r - i)$-complex.

In particular, taking $i = 0$ and $B = \{\emptyset\}$ implies that every $(\varepsilon, \xi, f, r)$-supercomplex is also an $(\varepsilon, \xi, f, r)$-complex. Moreover, the above definition ensures that if $G$ is a supercomplex and $b, b' \in G^{(i)}$, then $G(b) \cap G(b')$ is also a supercomplex (cf. Proposition 5.5).

In Section 4.3, we will give some examples of supercomplexes. As mentioned above, the following lemma allows us to ‘boost’ the regularity parameters (and thus deduce results with ‘effective’ bounds). It is an easy consequence of our Boost lemma (Lemma 6.3). The key to the proof is that we can (probabilistically) choose some $Y \subseteq G^{(f)}$ so that the parameters of $G[Y]$ in Definition 4.1(i) are better than those of $G$, i.e. the resulting distribution of $f$-sets is more uniform.

Lemma 4.4. Let $1/n \leq \varepsilon, \xi, 1/f$ and $r \in [f - 1]$ with $2(2\sqrt{\varepsilon})^r \varepsilon \leq \xi$. Let $\xi' := 0.9(1/4)^{(f/r)} \xi$. If $G$ is an $(\varepsilon, \xi, f, r)$-complex on $n$ vertices, then $G$ is an $(n^{-1/3}, \xi', f, r)$-complex. In particular, if $G$ is an $(\varepsilon, \xi, f, r)$-supercomplex, then it is a $(2n^{-1/3}, \xi', f, r)$-supercomplex.

4.2. The main complex decomposition theorem. The statement of our main complex decomposition theorem involves the concept of ‘well separated’ decompositions. This is crucial for our inductive proof to work in the context of $F$-decompositions.

Definition 4.5 (well separated). Let $F$ be an $r$-graph and let $\mathcal{F}$ be an $F$-packing (in some $r$-graph $G$). We say that $\mathcal{F}$ is $\kappa$-well separated if the following hold:

(WS1) for all distinct $F', F'' \in \mathcal{F}$, we have $|V(F') \cap V(F'')| < r$.

(WS2) for every $r$-set $e$, the number of $F' \in \mathcal{F}$ with $e \subseteq V(F')$ is at most $\kappa$.

We simply say that $\mathcal{F}$ is well separated if (WS1) holds.

For instance, any $K_f^{(r)}$-packing is automatically 1-well separated. Moreover, if an $F$-packing $\mathcal{F}$ is 1-well separated, then for all distinct $F', F'' \in \mathcal{F}$, we have $|V(F') \cap V(F'')| < r$. On the other hand, since $F$ might not be complete, we do not require $|V(F') \cap V(F'')| < r$ in (WS1) as this would make it impossible to find a well separated $F$-decomposition of $K_f^{(r)}$. The notion of being well-separated is a natural relaxation of this requirement, we discuss this in more detail after stating Theorem 4.7.

We now define $F$-divisibility and $F$-decompositions for complexes $G$ (rather than $r$-graphs $G$).

Definition 4.6. Let $F$ be an $r$-graph and $f := |V(F)|$. A complex $G$ is $F$-divisible if $G^{(r)}$ is $F$-divisible. An $F$-packing in $G$ is an $F$-packing in $G^{(r)}$ such that $V(F') \in G^{(f)}$ for all $F' \in \mathcal{F}$. Similarly, we say that $\mathcal{F}$ is an $F$-decomposition of $G$ if $\mathcal{F}$ is an $F$-packing in $G$ and $\mathcal{F}^{(r)} = G^{(r)}$.

Note that this implies that every copy $F'$ of $F$ used in an $F$-packing in $G$ is ‘supported’ by a clique, i.e. $G^{(r)}[V(F')] \cong K_f^{(r)}$.

We can now state our main complex decomposition theorem.

Theorem 4.7 (Main complex decomposition theorem). For all $r \in \mathbb{N}$, the following is true.

\[ (*)_r \quad \text{Let } 1/n \ll 1/\kappa, \varepsilon \ll 1/f \text{ and } f > r. \text{ Let } F \text{ be a weakly regular } r\text{-graph on } f \text{ vertices and let } G \text{ be an } F\text{-divisible } (\varepsilon, \xi, f, r)\text{-supercomplex on } n \text{ vertices. Then } G \text{ has a } \kappa\text{-well separated } F\text{-decomposition.} \]

Note that in light of Lemma 4.4, $(*)_r$ already holds if $\varepsilon \leq \frac{\xi}{2(2\sqrt{\varepsilon})^r}$. We will prove $(*)_r$ by induction on $r$ in Section 9. We do not make any attempt to optimise the values that we obtain for $\kappa$.

We now motivate Definitions 4.5 and 4.6. This involves the following additional concepts, which are also convenient later.
Lemma 9.2 shows that for every given $r$-graphs in a natural way. Moreover, observe that (WS2) is equivalent to the condition $\Delta(G) \leq \kappa$. Furthermore, if $F$ is a well separated $F$-packing in a complex $G$, then $F^{\leq}$ is a subcomplex of $G$ by Definition 4.6. Clearly, we have $F^{(r)} \subseteq F^{(r)}$, but in general equality does not hold. On the other hand, if $F$ is an $F$-decomposition of $G$, then $F^{(r)} = G^{(r)}$ which implies $F^{(r)} = F^{(r)}$.

We now discuss (WS1). During our proof, we will need to find an $F$-packing which covers a given set of edges. This gives rise to the following task of ‘covering down locally’. Indeed, if $F$ is a well-separated $F$-packing, then the $f$-graph $\{V(F') : F' \in F\}$ is simple. Hence, observe that (WS2) is equivalent to the condition $\Delta(G) \leq \kappa$. Furthermore, if $F$ is a well separated $F$-packing in a complex $G$, then $F^{\leq}$ is a subcomplex of $G$ by Definition 4.6. Clearly, we have $F^{(r)} \subseteq F^{(r)}$, but in general equality does not hold. On the other hand, if $F$ is an $F$-decomposition of $G$, then $F^{(r)} = G^{(r)}$ which implies $F^{(r)} = F^{(r)}$.

Finally, we discuss why we prove Theorem 4.7 for weakly regular $r$-graphs. Most importantly, the ‘regularity’ of the degrees will be crucial for the construction of our absorbers (most notably in Lemma 8.25). Beyond that, weakly regular graphs also have useful closure properties (cf. Proposition 5.3): they are closed under taking link graphs and divisibility is inherited by link graphs in a natural way.

We prove Theorem 4.7 in Sections 6–8 and 9.1. As described in Section 1.7, we generalise this to arbitrary $F$ via Lemma 9.2 (proved in Section 9.2) and Lemma 9.4 (proved in Section 11): Lemma 9.2 shows that for every given $r$-graph $F$, there is a weakly regular $r$-graph $F^*$ which
has an $F$-decomposition. Lemma 9.4 then complements this by showing that every $F$-divisible $r$-graph $G$ can be transformed into an $F^*$-divisible $r$-graph $G'$ by removing a sparse $F$-decomposable subgraph of $G$.

4.3. Applications. As the definition of a supercomplex covers a broad range of settings, we give some applications here. We will use Examples 4.9, 4.10 and 4.12 in Section 9 to prove Theorems 1.1, 1.2, 1.4, 1.6 and 1.7. We will also see that random subcomplexes of a supercomplex are again supercomplexes with appropriately adjusted parameters (see Corollary 5.19).

**Example 4.9.** Let $1/n \ll 1/f$ and $r \in [f-1]$. It is straightforward to check that the complete complex $K_n$ is a $(0, 0.99/f, f, r)$-supercomplex.

Recall that $(c, h, p)$-typicality was defined in Section 1.

**Example 4.10** (Typicality). Suppose that $1/n \ll c, p, 1/f$, that $r \in [f-1]$ and that $G$ is a $(c, 2^{r(f+1)}, p)$-typical $r$-graph on $n$ vertices. Then $G^{(s)}$ is an $(\varepsilon, \xi, f, r)$-supercomplex, where
\[
\varepsilon := 2^{f-r}+1c/(f-r)! \quad \text{and} \quad \xi := (1-2^{r+1}c)p^{2^f(r+1)}/f!.
\]

**Proof.** Let $i \in [r]_0$ and $B \subseteq G^{(i)}$ with $1 \leq |B| \leq 2^i$. Let $G_B := \bigcap_{b \in B} G^{(b)}$ and $n_B := |V(G) \setminus \bigcup B|$. Let $e \in G^{(r-1)}$. To estimate $|G_B^{(f-i)}(e)|$, we let $Q_e$ be the set of ordered $(f-r)$-tuples $(v_1, \ldots, v_{f-r})$ consisting of distinct vertices in $V(G) \setminus (e \cup \bigcup B)$ such that for all $b \in B$, $\{b \cup \{v_1, \ldots, v_{r-1}\}\} \subseteq G$. Note that $|G_B^{(f-i)}(e)| = |Q_e|/(f-r)!$. We estimate $|Q_e|$ by picking $v_1, \ldots, v_{f-r}$ sequentially. So let $j \in [f-r]$ and suppose that we have already chosen $v_1, \ldots, v_{j-1} \notin e \cup \bigcup B$ such that $\{b \cup \{v_1, \ldots, v_{j-1}\}\} \subseteq G$ for all $b \in B$. Let $D_j = \bigcup_{b \in B} \{b \cup \{v_1, \ldots, v_{j-1}\}\}$. Thus the possible values for $v_j$ are precisely the vertices in $\bigcap_{S \subseteq D_j} G(S)$. Note that $d_j := |D_j| \leq \binom{|B|}{r-1}$, and that $d_j$ only depends on the intersection pattern of the $b \in B$, but not on our previous choice of $e$ and $v_1, \ldots, v_{j-1}$. Since $G$ is typical, we have $(1 \pm c)p^{d_j}/n$ choices for $v_j$. We conclude that
\[
|Q_e| = (1 \pm c)^{f-r}p^{\sum_{j=1}^{f-r} d_j/(f-r)!} = (1 \pm 2^{f-r}+1c)d_B(f-r)!n_B^{f-r},
\]
where $d_B := p^{\sum_{j=1}^{f-r} d_j/(f-r)!}$. Thus, $G_B$ is $(2^{f-r}+1cd_B, d_B, f-i, r-i)$-regular. Since $\sum_{j=1}^{f-r} \binom{r+1}{r-j} = (f-1) - 1$ we have $1/(f-r)! \geq d_B \geq p^{\binom{f}{r-i}+1}/(f-r)! \geq p^2\binom{f}{r-i}/(f-r)!$. Similarly, we deduce that $G_B$ is $(1-2^{r-f-r}+1c)d_B, f-i, r-i)$-extendable. Moreover, we have
\[
|G_B^{(f-r-2i)}(e)| \geq \frac{(1-2^{f-r-2i}+1c)p^{2^f(r+1-i)}/(f-i)!}{(f-i)!} n_B^{f-i} \geq \xi^i n_B^{f-i}.
\]
Thus, $G_B$ is $(\xi, f+r-2i, r-i)$-dense. We conclude that $G_B$ is an $(\varepsilon, \xi, f-i, r-i)$-complex.

**Example 4.11** (Partite graphs). Let $1/N \ll 1/k$ and $2 = r < f \leq k-6$. Let $V_1, \ldots, V_k$ be vertex sets of size $N$ each. Let $G$ be the complete $k$-partite 2-graph on $V_1, \ldots, V_k$. It is straightforward to check that $G^{(s)}$ is a $(0, k, f, 2)$-supercomplex. Thus, using Theorem 4.7, we can deduce that $G$ has an $F$-decomposition if it is $F$-divisible. To obtain a minimum degree version (and more generally, a resilience version) along the lines of Theorems 1.4 and 9.3, one can argue similarly as in the proof of Theorem 9.3 (cf. Section 9).

Results on (fractional) decompositions of dense $f$-partite 2-graphs into $f$-cliques are proved in [8, 10, 35]. These have applications to the completion of partial (mutually orthogonal) Latin squares.

**Example 4.12** (The matching case). Consider $1 = r < f$. Let $G$ be a $f$-graph on $n$ vertices such that the following conditions hold for some $0 < \varepsilon \leq t \leq 1$:
- for some $d \geq \xi - \varepsilon$, $|G(v)| = (d \pm \varepsilon)n^{f-1}$ for all $v \in V(G)$;
- every vertex is contained in at least $\xi n^f$ copies of $K^{(f)}_{f+1}$;
- $|G(v) \cap G(w)| \geq \xi n^{f-1}$ for all $v, w \in V(G)$.

Then $G^{(s)}$ is an $(\varepsilon, \xi - \varepsilon, f, 1)$-supercomplex.
4.4. Disjoint decompositions and designs. Recall that a $K_f^{(r)}$-decomposition of an $r$-graph is an $(K_f^{(r)}, 1)$-design. We now discuss consequences of our main theorem for general $(K_f^{(r)}, \lambda)$-designs. We can deduce from Theorem 4.7 that there are many $f$-disjoint $K_f^{(r)}$-decompositions, see Corollary 4.14. This will easily follow from $(\ast)$, and the next result.

**Proposition 4.13.** Let $1/n \ll \varepsilon, \xi, 1/f$ and $r \in [f - 1]$. Suppose that $G$ is an $(\varepsilon, \xi, f, r)$-supercomplex on $n$ vertices. Let $Y_{\text{used}}$ be an $f$-graph on $V(G)$ with $\Delta_r(Y_{\text{used}}) \leq \varepsilon n^{f-r}$. Then $G - Y_{\text{used}}$ is a $(2^{r+2} \varepsilon, \xi - 2^{3r+1} \varepsilon, f, r)$-supercomplex.

We will apply this when $K_1, \ldots, K_r$ are $K_f^{(r)}$-packings in some complex $G$, in which case $Y_{\text{used}} := \bigcup_{j \in [r]} K_j^{(f)}$ satisfies $\Delta_r(Y_{\text{used}}) \leq t$.

**Proof.** Fix $i \in [r]$ and $B \subseteq G^{(i)}$ with $1 \leq |B| \leq 2^i$. Let $n_B := n - |\bigcup B|$, $G' := \bigcap_{b \in B} G(b)$ and $G'' := \bigcap_{b \in B}(G - Y_{\text{used}}(b))$. By assumption, there exists $Y \subseteq G''^{(i-1)}$ such that $G[Y]$ is a full $(\varepsilon, \xi, f-i, r-i)$-complex. We claim that $G''[Y]$ is a full $(2^{r+2} \varepsilon, \xi - 2^{3r+1} \varepsilon, f-i, r-i)$-complex.

First, there is some $d \geq \xi$ such that $G'[Y]$ is $(\varepsilon, d, f-i, r-i)$-regular. Let $e \in G''^{(r-i)}$. We clearly have $|G''[Y][f-i](e)| \leq |G'[Y][f-i](e)| \leq (d + \varepsilon)n_B^{f-r}$. Moreover, for each $b \in B$, there are at most $\varepsilon n^{f-r}$ $f$-sets in $Y_{\text{used}}$ that contain $e \cup b$. Thus, $|G''[Y][f-i](e)| \geq (d - \varepsilon)n_B^{f-r} - |B|\varepsilon n^{f-r} \geq (d - \varepsilon - 1.1 \cdot 2^i \varepsilon)n_B^{f-r}$. Thus, $G''[Y]$ is $(2^{r+2} \varepsilon, d, f-i, r-i)$-regular.

Next, by assumption we have that $G'[Y]$ is $(\xi, f + r - 2i, r-i)$-dense. Let $e \in G''^{(r-i)}$. For each $b \in B$, we claim that the number $N_b$ of $(f + r - i)$-sets in $V(G)$ that contain $e \cup b$ and also contain some $f$-set from $Y_{\text{used}}$ is at most $2^i \varepsilon n^{f-r-i}$. Indeed, for any $k \in \{1, \ldots, r\}$ and any $K \in \mathcal{Y}_{\text{used}}$ with $|(e \cup b) \cap K| = k$, there are at most $n_k^{r-i} \Delta_r(Y_{\text{used}}) \leq (\xi) \varepsilon n^{f-r-k}$ $f$-sets $K \in Y_{\text{used}}$ with $|(e \cup b) \cap K| = k$. Hence, $N_b \leq \sum_{k=1}^{n_k^{r-i}} \varepsilon n^{f-r-k} \leq 2^i \varepsilon n^{f-r-i}$. We then deduce that $|G''[Y][f+r-2i](e)| \geq \xi n_B^{f-i} - |B|2^i \varepsilon n^{f-r-i} \geq \xi n_B^{f-i} - \varepsilon 2^{2r+i}n^{f-i} \geq (\xi - 2^{3r+1} \varepsilon)n_B^{f-i}$.

Finally, since $G''[Y][r-i] = G'[Y][r-i]$, $G''[Y]$ is $(\xi, f-i, r-i)$-extendable. Thus, $G - Y_{\text{used}}$ is a $(2^{r+2} \varepsilon, \xi - 2^{3r+1} \varepsilon, f, r)$-supercomplex. □

Clearly, any complex $G$ on $n$ vertices can have at most $n^{f-r}/(f-r)!$ $f$-disjoint $K_f^{(r)}$-decompositions. Moreover, if $G$ has $\lambda$ $f$-disjoint $K_f^{(r)}$-decompositions, then $G^{(r)}$ has a $(K_f^{(r)}, \lambda)$-design.

**Corollary 4.14.** Let $1/n \ll \varepsilon, \xi, 1/f$ and $r \in [f - 1]$ with $10 \cdot 7^r \varepsilon \leq \xi$ and assume that $(\ast)_r$ is true. Suppose that $G$ is a $K_f^{(r)}$-divisible $(\varepsilon, \xi, f, r)$-supercomplex on $n$ vertices. Then $G$ has $\varepsilon n^{f-r}$ $f$-disjoint $K_f^{(r)}$-decompositions. In particular, $G^{(r)}$ has a $(K_f^{(r)}, \lambda)$-design for all $1 \leq \lambda \leq \varepsilon n^{f-r}$.

**Proof.** Suppose that $K_1, \ldots, K_t$ are $f$-disjoint $K_f^{(r)}$-decompositions of $G$, where $t \leq \varepsilon n^{f-r}$. By Proposition 4.13 (and the subsequent remark), $G - \bigcup_{j \in [r]} K_j^{(f)}$ is a $(2^{r+2} \varepsilon, \xi - 2^{3r+1} \varepsilon, f, r)$-supercomplex. Since $2(2\sqrt{\varepsilon})^{2^{r+2} \varepsilon} \leq \xi - 2^{3r+1} \varepsilon$, $G - \bigcup_{j \in [r]} K_j^{(f)}$ has a $K_f^{(r)}$-decomposition $K_{t+1}$ by (the remark after) $(\ast)_r$, which is $f$-disjoint from $K_1, \ldots, K_t$. □

Note that Corollary 4.14 together with Example 4.9 implies that whenever $1/n \ll 1/f$ and $K_n^{(r)}$ is $K_f^{(r)}$-divisible, then $K_n^{(r)}$ has a $(K_f^{(r)}, \lambda)$-design for all $1 \leq \lambda \leq 1/11 \cdot n^{f-r}$, which improves the bound $\lambda/n^{f-r} \ll 1$ in [23].

Using (WS2), we can deduce that there are many $f$-disjoint $F$-decompositions of a supercomplex. This will be an important tool in the proof of the Cover down lemma (Lemma 7.7), where we will find many candidate $F$-decompositions and then pick one at random.

**Corollary 4.15.** Let $1/n \ll \varepsilon \ll \xi, 1/f$ and $r \in [f - 1]$ and assume that $(\ast)_r$ is true. Let $F$ be a weakly regular $r$-graph on $f$ vertices. Suppose that $G$ is an $F$-divisible $(\varepsilon, \xi, f, r)$-supercomplex on $n$ vertices. Then the number of pairwise disjoint $1/\varepsilon$-well separated $F$-decompositions of $G$ is at least $\varepsilon^2 n^{f-r}$. □
Proof. Suppose that $F_1, \ldots, F_i$ are $f$-disjoint $1/\varepsilon$-well separated $F$-decompositions of $G$, where $t \leq \varepsilon^2 n^{f-r}$. Let $Y_{used} := \bigcup_{j \in [i]} F_{j}^{\leq (f)}$. By (WS2), we have $\Delta_r(Y_{used}) \leq t/\varepsilon \leq \varepsilon n^{f-r}$. Thus, by Proposition 5.3, $G - Y_{used}$ is an $F$-divisible $(2^{f+2} \varepsilon, \xi - 2^{r+1} \varepsilon, f, r)$-supercomplex and thus has a $1/\varepsilon$-well separated $F$-decomposition $F_{i+1}$ by $(*)_r$, which is $f$-disjoint from $F_1, \ldots, F_i$. □

5. Tools

5.1. Basic tools. We will often use the following ‘handshaking lemma’ for $r$-graphs: Let $G$ be an $r$-graph and $0 \leq i \leq k \leq r - 1$. Then for every $S \in \binom{V(G)}{i}$ we have

\[(5.1) \quad |G(S)| = \left(\frac{r - i}{r - k}\right) \sum_{T \in \binom{V(G)}{k}} |G(T)|.\]

Fact 5.1. Let $L$ be an $r$-graph on $n$ vertices with $\Delta(L) \leq \gamma n$. Then for each $i \in [r - 1]_0$, we have $\Delta_i(L) \leq \gamma n^{r - i}/(r - i)!$, and for each $S \in \binom{V(L)}{i}$, we have $\Delta(L(S)) \leq \gamma n$.

Proposition 5.2. Let $F$ be an $r$-graph. Then there exist infinitely many $n \in \mathbb{N}$ such that $K_n^{(r)}$ is $F$-divisible. 

Proof. Let $p := \prod_{i=0}^{r-1} \text{Deg}(F)_i$. We will show that for every $a \in \mathbb{N}$, if we let $n = r!a p + r - 1$ then $K_n^{(r)}$ is $F$-divisible. Clearly, this implies the claim. In order to see that $K_n^{(r)}$ is $F$-divisible, it is sufficient to show that $p \mid \binom{n-i}{r-i}$ for all $i \in [r-1]_0$. It is easy to see that this holds for the above choice of $n$. □

The following proposition shows that the class of weakly regular uniform hypergraphs is closed under taking link graphs.

Proposition 5.3. Let $F$ be a weakly regular $r$-graph and let $i \in [r - 1]$. Suppose that $S \in \binom{V(F)}{i}$ and that $F(S)$ is non-empty. Then $F(S)$ is a weakly regular $(r - i)$-graph and $\text{Deg}(F(S))_j = \text{Deg}(F)_j + i$ for all $j \in [r - i - 1]_0$.

Proof. Let $s_0, \ldots, s_{r-1}$ be such that $F$ is weakly $(s_0, \ldots, s_{r-1})$-regular. Note that since $F$ is non-empty, we have $s_j > 0$ for all $j \in [r - 1]_0$ (and the $s_j$’s are unique). Consider $j \in [r - i - 1]_0$. For all $T \in \binom{V(F(S))}{j}$, we have $|F(S)(T)| = |F(S \cup T)| \in \{0, s_1, \ldots, s_r\}$. Hence, $F(S)$ is weakly $(s_1, \ldots, s_{r-1})$-regular. Since $F$ is non-empty, we have $\text{Deg}(F) = (s_0, \ldots, s_{r-1})$, and since $F(S)$ is non-empty too by assumption, we have $\text{Deg}(F(S)) = (s_1, \ldots, s_{r-1})$. Therefore, $\text{Deg}(F(S))_j = \text{Deg}(F)_j + i$ for all $j \in [r - i - 1]_0$. □

We now list some useful properties of well separated $F$-packings.

Fact 5.4. Let $G$ be a complex and $F$ an $r$-graph on $f > r$ vertices. Suppose that $F$ is a $\kappa$-well separated $F$-packing (in $G$) and $F'$ is a $\kappa'$-well separated $F$-packing (in $G$). Then the following hold.

(i) $\Delta(\mathcal{F}^{\leq (r+1)}) \leq \kappa(f - r)$.
(ii) If $\mathcal{F}^{(r)}$ and $\mathcal{F}'^{(r)}$ are edge-disjoint and $\mathcal{F}$ and $\mathcal{F}'$ are $(r + 1)$-disjoint, then $\mathcal{F} \cup \mathcal{F}'$ is a $(\kappa + \kappa')$-well separated $F$-packing (in $G$).
(iii) If $\mathcal{F}$ and $\mathcal{F}'$ are $r$-disjoint, then $\mathcal{F} \cup \mathcal{F}'$ is a $\max\{\kappa, \kappa'\}$-well separated $F$-packing (in $G$).

5.2. Some properties of supercomplexes. We first state two basic properties of supercomplexes that we will use in Section 8 to construct absorbers.

Proposition 5.5. Let $G$ be an $(\varepsilon, \xi, f, r)$-supercomplex and let $B \subseteq G^{(i)}$ with $1 \leq |B| \leq 2^i$ for some $i \in [r]_0$. Then $\bigcap_{b \in B} G(b)$ is an $(\varepsilon, \xi, f - i, r - i)$-supercomplex.

Proof. Let $i' \in [r - i]_0$ and $B' \subseteq \bigcap_{b \in B} G(b)^{(i')}$ with $1 \leq |B'| \leq 2^{i'}$. Let $B^* := \{b \cup b' : b \in B, b' \in B'\}$. Note that $B^* \subseteq G^{(i + i')}$ and $|B^*| \leq 2^{i + i'}$. Thus, $\bigcap_{b \in B^*} (\bigcap_{b' \in B'} G(b')) = \bigcap_{b' \in B^*} G(b^*)$. □
is an \((\varepsilon, \xi, f - i - i', r - i - i')\)-complex by Definition 4.3, as required.

\[\square\]

**Fact 5.6.** If \(G\) is an \((\varepsilon, \xi, f, r)\)-supercomplex, then for all distinct \(e, e' \in G^{(r)}\), we have \(|G^{(f)}(e) \cap G^{(f)}(e')| \geq (\xi - \varepsilon)(n - 2r)^{f - r}\).

In what follows, we gather tools that show that supercomplexes are robust with respect to small perturbations. We first bound the number of \(f\)-sets that can affect a given edge \(e\). We provide two bounds, one that we use when optimising our bounds (e.g. in the derivation of Theorem 1.4) and a more convenient one that we use when the precise value of the parameters is irrelevant (e.g. in the proof of Proposition 5.9).

**Proposition 5.7.** Let \(f, r' \in \mathbb{N}\) and \(r \in \mathbb{N}_0\) with \(f > r\). Let \(L\) be an \(r'\)-graph on \(n\) vertices with \(\Delta(L) \leq \gamma n\). Then every \(e \in (V^{(L)})^2\) that does not contain any edge of \(L\) is contained in at most \(2^{r'}, \frac{r}{(r-\gamma)}\gamma n^{f-r}\) \(f\)-sets of \(V(L)\) that contain an edge of \(L\).

**Proof.** Consider any \(e \in (V^{(L)})^2\) that does not contain any edge of \(L\). For a fixed edge \(e' \in \mathcal{L}\) with \(|e \cup e'| \leq f\) and \(|e \cap e'| = i\), there are at most \(\sum_{i=1}^{r'} \gamma n^{i-r}(f-r-i)!\) \(f\)-sets of \(\mathcal{L}\) that contain both \(e\) and \(e'\). Moreover, since \(e' \not\subseteq e\), we have \(i < r'\). Hence, by Fact 5.1, there are at most \(\sum_{i=1}^{r'} \gamma n^{i-r}(f-r-i)!\) edges \(e' \in \mathcal{L}\) with \(|e \cap e'| = i\). Let \(s := \max\{r + r' - f, 0\}\). Thus, the number of \(f\)-sets in \(V(L)\) that contain \(e\) and an edge of \(L\) is at most

\[
\sum_{i=s}^{r'} \gamma n^{i-r}(f-r-i)! = \gamma n^{f-r} \sum_{i=s}^{r'} \frac{r-i}{(f-r-i)!}.
\]

Clearly, \(\frac{r-i}{(f-r-i)!} \leq 1\), and we can bound \(\sum_{i=s}^{r'} \frac{r-i}{(f-r-i)!} \leq 2^{r'}\). Also, using Vandermonde’s convolution, we have \(\sum_{i=s}^{r'} \frac{r-i}{(f-r-i)!} \leq \frac{r}{(r-\gamma)}\gamma n^{f-r}\).

\[\square\]

**Fact 5.8.** Let \(0 \leq i \leq r\). For a complex \(G\), an \(r\)-graph \(H\) and \(B \subseteq G^{(i)}\), we have

\[
\bigcap_{b \in B} (G - H)(b) = \bigcap_{b \in B} G(b) - H - \bigcup_{S \cup \mathcal{B}} H(S) - \bigcup_{S \cup \mathcal{B}} H(S) - \cdots - \bigcup_{S \cup \mathcal{B}} H(b).
\]

If \(B \subseteq (G - H)^{(i)}\), then both sides are empty.

**Proposition 5.9.** Let \(f, r' \in \mathbb{N}\) and \(r \in \mathbb{N}_0\) with \(f > r\) and \(r' \geq r\). Let \(G\) be a complex on \(n \geq 2r^{f+1}\) vertices and let \(H\) be an \(r'-\)graph on \(V(G)\) with \(\Delta(H) \leq \gamma n\). Then the following hold:

(i) If \(G\) is \((\varepsilon, d, f, r)\)-regular, then \(G - H\) is \((\varepsilon + 2^r\gamma, d, f, r)\)-regular.

(ii) If \(G\) is \((\xi, f, r)\)-dense, then \(G - H\) is \((\xi - 2^r\gamma, f, r)\)-dense.

(iii) If \(G\) is \((\xi, f, r)\)-extendable, then \(G - H\) is \((\xi - 2^r\gamma, f, r)\)-extendable.

(iv) If \(G\) is an \((\varepsilon, \xi, f, r)\)-complex, then \(G - H\) is an \((\varepsilon + 2^r\gamma, \xi - 2^r\gamma, f, r)\)-complex.

(v) If \(G\) is an \((\varepsilon, \xi, f, r)\)-supercomplex, then \(G - H\) is an \((\varepsilon + 2^r\gamma + 1, \xi - 2^r\gamma + 1, f, r)\)-supercomplex.

**Proof.** (i)–(iii) follow directly from Proposition 5.7. (iv) follows from (i)–(iii). To see (v), suppose that \(i \in [r]\) and \(B \subseteq (G - H)^{(i)}\) with \(1 \leq |B| \leq 2^i\). By assumption, \(\bigcap_{b \in B} G(b)\) is an \((\varepsilon, \xi, f - i, r - i)\)-complex. By Fact 5.8, we can obtain \(\bigcap_{b \in B} (G - H)(b)\) from \(\bigcap_{b \in B} G(b)\) by repeatedly deleting an \((r' - |S|)\)-graph \(H(S)\), where \(S \subseteq b \in B\). There are at most \(\sum_{|S|=r'} |G^{(f)}(e)| \leq 2^i\) such graphs. Unless \(|S| = r'\), we have \(\Delta(H(S)) \leq 2n + 2 = 2\gamma n - 2|B|\) by Fact 5.1. Note that if \(|S| = r'\), then \(S \subseteq B\) and hence \(H(S)\) is empty, in which case we can ignore its removal. Thus, a repeated application of (iv) (with \(r' - |S|, r - i\) playing the roles of \(r', r\)) shows that \(\bigcap_{b \in B} (G - H)(b)\) is an \((\varepsilon + 2^r\gamma + 1, \xi - 2^r\gamma + 1, f - i, r - i)\)-complex.

\[\square\]
5.3. Probabilistic tools. The following Chernoff-type bounds form the basis of our concentration results that we use for probabilistic arguments.

**Lemma 5.10** (see [22, Corollary 2.3, Corollary 2.4, Remark 2.5 and Theorem 2.8]). Let $X$ be the sum of $n$ independent Bernoulli random variables. Then the following hold.

(i) For all $t \geq 0$, $\mathbb{P}(|X - \mathbb{E}X| \geq t) \leq 2e^{-2t^2/n}$.

(ii) For all $0 \leq \varepsilon \leq 3/2$, $\mathbb{P}(|X - \mathbb{E}X| \geq \varepsilon \mathbb{E}X) \leq 2e^{-e^2\mathbb{E}X/3}$.

(iii) If $t \geq \mathbb{E}X$, then $\mathbb{P}(X \geq t) \leq e^{-t}$.

We will also use the following simple result.

**Proposition 5.11** (Jain, see [38, Lemma 8]). Let $X_1, \ldots, X_n$ be Bernoulli random variables such that, for any $i \in [n]$ and any $x_1, \ldots, x_{i-1} \in \{0,1\}$,

$$\mathbb{P}(X_i = 1 \mid X_1 = x_1, \ldots, X_{i-1} = x_{i-1}) \leq p.$$  

Let $B \sim B(n, p)$ and $X := X_1 + \cdots + X_n$. Then $\mathbb{P}(X \geq a) \leq \mathbb{P}(B \geq a)$ for any $a \geq 0$.

**Lemma 5.12**. Let $1/n \ll p, \alpha, 1/a, 1/B$. Let $I$ be a set of size at least $an^a$ and let $(X_i)_{i \in I}$ be a family of Bernoulli random variables with $\mathbb{P}(X_i = 1) \geq p$. Suppose that $I$ can be partitioned into at most $Bn^{a-1}$ sets $I_1, \ldots, I_k$ such that for each $j \in [k]$, the variables $(X_i)_{i \in I_j}$ are independent. Let $X := \sum_{i \in I} X_i$. Then we have

$$\mathbb{P}(\lvert X - \mathbb{E}X \rvert \geq n^{-1/5} \mathbb{E}X) \leq e^{-n^{1/6}}.$$  

**Proof.** Let $J_1 := \{j \in [k] : \lvert I_j \rvert \geq n^{3/5}\}$ and $J_2 := [k] \setminus J_1$. Let $Y_j := \sum_{i \in I_j} X_i$ and $\varepsilon := n^{-1/5}$. Suppose that $\lvert Y_j - \mathbb{E}Y_j \rvert \leq 0.9 \mathbb{E}Y_j$ for all $j \in J_1$. Then

$$\lvert X - \mathbb{E}X \rvert \leq \sum_{j \in [k]} |Y_j - \mathbb{E}Y_j| \leq n^{3/5} \cdot Bn^{a-1} + \sum_{j \in J_1} 0.9 \mathbb{E}Y_j \leq Bn^{a-2/5} + 0.9 \mathbb{E}X \leq \varepsilon \mathbb{E}X.$$  

Thus,

$$\mathbb{P}(\lvert X - \mathbb{E}X \rvert \geq \varepsilon \mathbb{E}X) \leq \sum_{j \in J_1} \mathbb{P}(|Y_j - \mathbb{E}Y_j| \geq 0.9 \mathbb{E}Y_j) \leq \sum_{j \in J_1} 2e^{-0.81 \mathbb{E}Y_j/3} \leq 2Bn^{a-1}e^{-0.27n^{-2/5}pn^{3/5}} \leq e^{-n^{1/6}}.$$  

Similarly as in [20], Lemma 5.12 can be conveniently applied in the following situation: We are given an $r$-graph $H$ on $n$ vertices and $H'$ is a random subgraph of $H$, where every edge of $H$ survives with some probability $\geq p$. The following folklore observation allows us to apply Lemma 5.12 in order to obtain a concentration result for $|H'|$.

**Fact 5.13.** Every $r$-graph on $n$ vertices can be decomposed into $rn^{r-1}$ matchings.

**Corollary 5.14.** Let $1/n \ll p, 1/r, \alpha$. Let $H$ be an $r$-graph on $n$ vertices with $\lvert H \rvert \geq an^a$. Let $H'$ be a random subgraph of $H$, where each edge of $H$ survives with some probability $\geq p$. Moreover, suppose that for every matching $M$ in $H$, the edges of $M$ survive independently. Then we have

$$\mathbb{P}(|H'| - \mathbb{E}|H'| \geq n^{-1/5} \mathbb{E}|H'|) \leq e^{-n^{1/6}}.$$  

Whenever we apply Corollary 5.14, it will be clear that for every matching $M$ in $H$, the edges of $M$ survive independently, and we will not discuss this explicitly.

**Lemma 5.15.** Let $1/n \ll p, 1/r$. Let $H$ be an $r$-graph on $n$ vertices. Let $H'$ be a random subgraph of $H$, where each edge of $H$ survives with some probability $\leq p$. Suppose that for every matching $M$ in $H$, the edges of $M$ survive independently. Then we have

$$\mathbb{P}(|H'| \geq 7pn^r) \leq rn^{r-1}e^{-7pn/r}.$$  

**Proof.** Partition $H$ into at most $rn^{r-1}$ matchings $M_1, \ldots, M_k$. For each $i \in [k]$, by Lemma 5.10(iii) we have $\mathbb{P}(|H' \cap M_i| \geq 7pn/r) \leq e^{-7pn/r}$ since $\mathbb{E}|H' \cap M_i| \leq pn/r$. $\square$
5.4. Random subsets and subgraphs. In this subsection, we apply the above tools to obtain basic results about random subcomplexes. The first one deals with taking a random subset of the vertex set, and the second one considers the complex obtained by randomly sparsifying $G^{(r)}$.

**Proposition 5.16.** Let $1/n < \varepsilon, \xi, 1/f$ and $1/n < \gamma < \mu, 1/f$ and $r \in [f - 1]_0$. Let $G$ be an $(\varepsilon, \xi, f, r)$-complex on $n$ vertices. Suppose that $U$ is a random subset of $V(G)$ obtained by including every vertex from $V(G)$ independently with probability $\mu$. Then with probability at least $1 - e^{-n^{1/3}}$, the following holds: for any $W \subseteq V(G)$ with $|W| \leq \gamma n$, $G[U \Delta W]$ is an $(\varepsilon + 2n^{-1/5} + \xi^{2/3}, \xi - n^{-1/5} - \xi^{2/3}, f, r)$-complex, where $\gamma := \max\{|W|/n, n^{-1/3}\}$.

**Proof.** If $G^{(r)}$ is empty, there is nothing to prove, so assume the contrary.

By assumption, there exists $Y \subseteq G^{(f)}$ such that $G[Y]$ is $(\varepsilon, d, f, r)$-regular for some $d \geq \xi$, $(\xi, f, r)$-dense and $(\xi, f, r)$-extendable. The latter implies that there exists $X \subseteq V(G)$ with $|X| \geq \xi n$ such that for all $e \in (X, Y)$, we have $|Ext_e| \geq \xi n^{f-r}$, where $Ext_e$ is the set of all $(f-r)$-sets $Q \subseteq V(G) \setminus e$ such that $(Q \cup e) \setminus \{e\} \subseteq G^{(r)}$.

First, by Lemma 5.10(i), with probability at least $1 - 2e^{-2n^{1/3}}$, we have $|U| = \mu n \pm n^{2/3}$, and with probability at least $1 - 2e^{-2n^{1/4}}$, $|X \cap U| \geq \mu |X| - |X|^{2/3}$.

**Claim 1:** For all $e \in G^{(r)}$, with probability at least $1 - e^{-n^{1/6}}$, $|G[Y]^{(f)}(e)[U]| = (d \pm (\varepsilon + 2n^{-1/5})((\mu n)^{f-r})$.

**Proof of claim:** Fix $e \in G^{(r)}$. Note that $E[G[Y]^{(f)}(e)[U]] = \mu^{f-r}|G[Y]^{(f)}(e)| = (d \pm \varepsilon)(\mu n)^{f-r}$. Viewing $G[Y]^{(f)}(e)$ as a $(f-r)$-graph and $G[Y]^{(f)}(e)[U]$ as a random subgraph, we deduce with Corollary 5.14 that

$$\mathbb{P}(|G[Y]^{(f)}(e)[U]| \neq (1 \pm n^{-1/5})(d \pm \varepsilon)(\mu n)^{f-r}) \leq e^{-n^{1/6}}.$$ 

**Claim 2:** For all $e \in G^{(r)}$, with probability at least $1 - e^{-n^{1/6}}$, $|G[Y]^{(f+r)}(e)[U]| \geq (\xi - n^{-1/5})(\mu n)^f$.

**Proof of claim:** Note that $E[G^{(f+r)}(e)[U]] = \mu^f|G^{(f+r)}(e)| \geq (\xi (\mu n))$. Viewing $G^{(f+r)}(e)$ as a $f$-graph and $G^{(f+r)}(e)[U]$ as a random subgraph, we deduce with Corollary 5.14 that

$$\mathbb{P}(|G^{(f+r)}(e)[U]| \leq (1 - n^{-1/5})(\xi (\mu n))^f \leq e^{-n^{1/6}}.$$ 

For $e \in (X, Y)$, let $Ext'_e$ be the random subgraph of $Ext_e$ containing all $Q \in Ext_e$ with $Q \subseteq U$.

**Claim 3:** For all $e \in (X, Y)$, with probability at least $1 - e^{-n^{1/6}}$, $|Ext'_e| \geq (\xi - n^{-1/5})(\mu n)^{f-r}$.

**Proof of claim:** Let $e \in (X, Y)$. Note that $E[Ext'_e] = \mu^{f-r}|Ext_e| \geq (\xi (\mu n)^{f-r}$. Again, Corollary 5.14 implies that

$$\mathbb{P}(|Ext'_e| \leq (1 - n^{-1/5})(\xi (\mu n)^{f-r}) \leq e^{-n^{1/6}}.$$ 

Hence, a union bound yields that with probability at least $1 - e^{-n^{1/7}}$, we have $|U| = \mu n \pm n^{2/3}$, $|X \cap U| \geq \mu |X| - |X|^{2/3}$ and the above claims hold for all relevant $e$ simultaneously. Assume that this holds for some outcome $U$. We now deduce the desired result deterministically. Let $W \subseteq V(G)$ with $|W| \leq \gamma n$. Define $G' := G[U \Delta W]$ and $n' := |U \Delta W|$. Note that $\mu n = (1 \pm 4\mu^{-1}\gamma)n'$. For all $e \in G^{(r)}$, we have

$$|G'[Y]^{(f)}(e)| = |G[Y]^{(f)}(e)[U]| + |W|n^{f-r} = (d \pm (\varepsilon + 2n^{-1/5} + |W|/\mu n^{f-r}))((\mu n)^{f-r})$$

$$= (d \pm (\varepsilon + 2n^{-1/5} + \mu^{-1}(f-r)\gamma))(1 \pm 2f-r4\mu^{-1}\gamma)n'^{f-r}$$

$$= (d \pm (\varepsilon + 2n^{-1/5} + \gamma^{2/3}))n'^{f-r}$$
Proposition 5.18.

and
\[|G'[Y]|^{(j+r)}(e) \geq |G[Y]|^{(j+r)}(e)[U]| - |W|n^{j-1}/(\mu n)^f \geq (\xi - n^{-1/5} - \frac{|W|}{\mu n})f \]
\[\geq (\xi - n^{-1/5} - \mu^{-f}\tilde{\gamma}) (1 - 2^f 4\mu^{-1}\tilde{\gamma}) n^{f-r} \geq (\xi - n^{-1/5} - \tilde{\gamma}^{2/3})n^{f-r},\]
so \(G'[Y]\) is \((\varepsilon + 2n^{-1/5} + \tilde{\gamma}^{2/3}, d, f, r)\)-regular and \((\xi - n^{-1/5} - \tilde{\gamma}^{2/3}, f + r, r)\)-dense.

Finally, let \(X' := (X \cap U) \setminus W\). Clearly, \(X' \subseteq V(G')\) and \(|X'| \geq (\xi - n^{-1/5} - \tilde{\gamma}^{2/3})n'\). Moreover, for every \(e \in (X', r)\), there are at least
\[|Eext_e| - |W|n^{f-r-1} \geq (\xi - n^{-1/5} - \tilde{\gamma}^{2/3})n^{f-r} \]
\((f - r)\)-sets \(Q \subseteq V(G') \setminus e\) such that \((Q,e) \setminus \{e\} \subseteq G'(r)\). Thus, \(G'\) (and therefore \(G'[Y]\)) is \((\xi - n^{-1/5} - \tilde{\gamma}^{2/3}, f, r)\)-extendable.

The next result is a straightforward consequence of Proposition 5.16 and the definition of a supercomplex.

Corollary 5.17. Let \(1/n \ll \gamma \ll \mu \ll \varepsilon \ll \xi, 1/f \) and \(r \in [f - 1]\). Let \(G\) be an \((\varepsilon, \xi, f, r)\)-supercomplex on \(n\) vertices. Suppose that \(U\) is a random subset of \(V(G)\) obtained by including every vertex from \(V(G)\) independently with probability \(\mu\). Then with probability \(|W| \leq \gamma n\), \(G[U \setminus W] \) is a \((2\varepsilon, \xi - \varepsilon, f, r)\)-supercomplex.

Next, we investigate the effect on \(G\) of inducing to a random subgraph \(H\) of \(G^{(r)}\). For our applications, we need to be able to choose edges with different probabilities. It turns out that under suitable restrictions on these probabilities, the relevant properties of \(G\) are inherited by \(G[H]\).

Proposition 5.18. Let \(1/n \ll \varepsilon, \gamma, p, \xi, 1/f \) and \(r \in [f - 1]\), \(i \in [r]_0\). Let
\[\xi' := 0.95\xi p^{2r} (f + r) \geq 0.95\xi p^{(8j)}\] and \(\gamma' := 1.1 \cdot 2^i \frac{(f + r)}{(f - r)} \cdot \gamma\).

Let \(G\) be a complex on \(n\) vertices and \(B \subseteq G^{(i)}\) with \(1 \leq |B| \leq 2^i\). Suppose that
\[G_B := \bigcap_{b \in B} G(b)\] is an \((\varepsilon, \xi, f - i, r - i)\)-complex.

Assume that \(P\) is a partition of \(G^{(r)}\) satisfying the following containment conditions:

(I) For every \(b \in B\), there exists a class \(\mathcal{E}_b \in \mathcal{P}\) such that \(b \cup e \in \mathcal{E}_b\) for all \(e \in G^{(r-i)}_B\).

(II) For every \(E \in \mathcal{P}\) there exists \(D_E \in \mathbb{N}_0\) such that for all \(Q \in G^{(r-i)}_B\), we have that \(|\{e \in E : \exists b \in B : e \subseteq b \cup Q\}| = D_E\).

Let \(\beta : \mathcal{P} \to [p, 1]\) assign a probability to every class of \(\mathcal{P}\). Now, suppose that \(H\) is a random subgraph of \(G^{(r)}\) obtained by independently including every edge of \(E\) in \(P\) with probability \(\beta(E)\) (for all \(E \in \mathcal{P}\)). Then with probability at least \(1 - e^{-n^{1/8}}\), the following holds: for all \(L \subseteq G^{(r)}\) with \(\Delta(L) \leq \gamma n\) and all \((r + 1)\)-graphs \(O\) on \(V(G)\) with \(\Delta(O) \leq f^{-5r} \gamma n\),
\[\bigcap_{b \in B} (G[H \triangle L] - O)(b) \text{ is a } (3\varepsilon + \gamma', \xi' - \gamma', f - i, r - i)\)-complex.\]

Note that (I) and (II) certainly hold if \(\mathcal{P} = \{G^{(r)}\}\).

Proof. If \(G^{(r-i)}_B\) is empty, then the statement is vacuously true. So let us assume that \(G^{(r-i)}_B\) is not empty. Let \(n_B := |V(G) \setminus \bigcup B| = |V(G_B)|\). By assumption, there exists \(Y \subseteq G^{(r-i)}_B\) such that \(G_B[Y]\) is \((\varepsilon, d_B, f - i, r - i)\)-regular for some \(d_B \geq \xi\), \((\xi, f + r - 2i, r - i)\)-dense and \((\xi, f - i, r - i)\)-extendable. Define
\[p_B := \left(\prod_{b \in B} \beta(\mathcal{E}_b)\right)^{-1} \prod_{E \in \mathcal{P}} (\beta(E))^{D_E}.\]
Note that \( p_B \geq p_{B|Y}^{\mathcal{R}_i} \geq p^{2r(f_r)} \) and thus \( p_B d_B \geq \xi' \). For every \( e \in G^{(r-i)}_B \), let
\[
Q_e := G_B[Y]^{(f-i)}(e) \quad \text{and} \quad \tilde{Q}_e := G_B[Y]^{(f-r+2i)}(e).
\]

By assumption, we have \( |Q_e| = (d_B \pm \varepsilon)n_f^{f-r} \) and \( |\tilde{Q}_e| \geq \xi n_f^{f-r} \) for all \( e \in G^{(r-i)}_B \). Moreover, since \( G_B[Y] \) is \((\xi, f-i, r-i)\)-extendable, there exists \( X \subseteq V(G_B) \) with \( |X| \geq \xi n_B \) such that for all \( e \in \binom{X}{r-1} \), we have \( |\text{Ext}_e| \geq \xi n_f^{f-r} \), where \( \text{Ext}_e \) is the set of all \((f-r)\) sets \( Q \subseteq V(G_B) \setminus e \) such that \( (Q_e \cup \{e\}) \subseteq G^{(r-i)}_B = G_B[Y]^{(r-i)} \).

We consider the following (random) subsets. For every \( e \in G^{(r-i)}_B \), let \( Q'_e \) contain all \( Q \in Q_e \) such that for all \( b \in B \), we have \((b, Q_e) \) \( \subseteq \{b \cup e \} \subseteq H \). Define \( \tilde{Q}'_e \) analogously with \( \tilde{Q}_e \) playing the role of \( Q_e \). For every \( e \in \binom{X}{r-1} \), let \( \text{Ext}'_e \) contain all \( Q \in \text{Ext}_e \) such that for all \( b \in B \) and \( e' \in \binom{Q_e}{r-i} \), we have \( b \cup e' \in H \).

**Claim 1:** For each \( e \in G^{(r-i)}_B \), with probability at least \( 1 - e^{-n_B^{1/6}} \), \( |Q'_e| = (p_B d_B \pm 3\varepsilon)n_f^{f-r} \).

**Proof of claim:** We view \( Q_e \) as a \((f-r)\)-graph and \( Q'_e \) as a random subgraph. Note that
\[
\mathbb{P}(\forall b \in B : b \cup e \in H) = \prod_{b \in B} \mathbb{P}(b \cup e \in H) = \prod_{b \in B} \beta(\mathcal{E}_b).
\]

Hence, we have for every \( Q \in Q_e \) that
\[
\mathbb{P}(Q \in Q'_e) = \frac{\mathbb{P}(\forall b \in B : (b, Q_e) \subseteq H))}{\mathbb{P}(\forall b \in B : b \cup e \in H)} \prod_{b \in B} \beta(\mathcal{E}_b)
= \left( \frac{\prod_{b \in B} \beta(\mathcal{E}_b)}{\prod_{e' \in G^{(f-r)} : \exists b \in B : e' \subseteq b, Q_e)} \right)^{-1} \prod_{e' \in H} \mathbb{P}(e' \in H) \prod_{b \in B} \beta(\mathcal{E}_b)
= \left( \frac{\prod_{b \in B} \beta(\mathcal{E}_b)}{\prod_{e \in \mathcal{P}} (\beta(\mathcal{E}))^{D(e)}} \right)^{-1} \prod_{e \in \mathcal{P}} (\beta(\mathcal{E}))^{D(e)} = p_B.
\]

Thus, \( \mathbb{E}|Q'_e| = p_B|Q_e| \). Hence, we deduce with Corollary 5.14 that with probability at least \( 1 - e^{-n_B^{1/6}} \) we have \( |Q'_e| = (1 \pm \varepsilon)|Q_e| = (p_B d_B \pm 3\varepsilon)n_f^{f-r} \).

**Claim 2:** For each \( e \in G^{(r-i)}_B \), with probability at least \( 1 - e^{-n_B^{1/6}} \), \( |\tilde{Q}'_e| \geq \xi n_f^{f-r} \).

**Proof of claim:** We view \( \tilde{Q}_e \) as a \((f-i)\)-graph and \( \tilde{Q}'_e \) as a random subgraph. Observe that for every \( Q \in \tilde{Q}_e \), we have
\[
\mathbb{P}(Q \in \tilde{Q}'_e) \geq \mathbb{P}_{B,(f-r)}^{(f-r)}(1 - 1) \geq p^{2r(f_r)}
\]
and thus \( \mathbb{E}|\tilde{Q}'_e| \geq p^{2r(f_r)}|\tilde{Q}_e| \geq \xi p^{2r(f_r)}n_f^{f-r} \). Thus, we deduce with Corollary 5.14 that with probability at least \( 1 - e^{-n_B^{1/6}} \) we have \( |\tilde{Q}'_e| \geq \xi n_f^{f-r} \).

**Claim 3:** For every \( e \in \binom{X}{r-1} \), with probability at least \( 1 - e^{-n_B^{1/6}} \), \( |\text{Ext}'_e| \geq \xi n_f^{f-r} \).

**Proof of claim:** We view \( \text{Ext}_e \) as a \((f-r)\)-graph and \( \text{Ext}'_e \) as a random subgraph. Observe that for every \( Q \in \text{Ext}_e \), we have
\[
\mathbb{P}(Q \in \text{Ext}'_e) \geq \mathbb{P}_{B,(f-r)}^{(f-r)}(1 - 1) \geq p^{2r(f_r)}
\]
and thus \( \mathbb{E}|\text{Ext}'_e| \geq p^{2r(f_r)}|\text{Ext}_e| \geq \xi p^{2r(f_r)}n_f^{f-r} \). Thus, we deduce with Corollary 5.14 that with probability at least \( 1 - e^{-n_B^{1/6}} \) we have \( |\text{Ext}'_e| \geq \xi n_f^{f-r} \).
Applying a union bound, we can see that with probability at least $1 - e^{-n^{1/8}}$, $H$ satisfies Claims 1–3 simultaneously for all relevant $e$.

Assume that this applies. We now deduce the desired result deterministically. Let $L \subseteq G^{(r)}$ be any graph with $\Delta(L) \leq \gamma n$ and let $O$ be any $(r + 1)$-graph on $V(G)$ with $\Delta(O) \leq f^{-5r} \gamma n$. Let $G' := \bigcap_{b \in B} (G[H \Delta L] - O)(b)$. First, we claim that $G'[\gamma]$ is $(3\varepsilon + \gamma', p_B d_B, f - i, r - i)$-regular. Consider $e \in G'[\gamma]^{(r-i)}$. We have that $|Q'_e| = (p_B d_B \pm 3\varepsilon)n_B^{f-r}$.

Claim 4: If $Q \in G'[\gamma]^{(r-i)}(e) \Delta Q'_e$, then there is some $b \in B$ such that $b \cup Q \cup e$ contains some edge from $L - \{b \cup e\}$ or $O$.

Proof of claim: Clearly, $Q \in G_B[Y]^{(r-i)}(e)$. First, suppose that $Q \in G'[\gamma]^{(r-i)}(e) - Q'_e$. Since $Q \notin Q'_e$, there exists $b \in B$ such that $(b, Q, \gamma) \setminus \{b \cup e\} \subseteq H$, that is, there is $e' \in (b, Q, \gamma) \setminus \{b \cup e\}$ with $e' \notin H$. But since $Q \in G'[\gamma]^{(r-i)}(e)$, we have $e' \in H \Delta L$. Thus, $e' \in L$. Next, suppose that $Q \in Q'_e - G'[\gamma]^{(r-i)}(e)$. Since $Q \notin G'[\gamma]^{(r-i)}(e)$, there exists $b \in B$ such that $b \cup Q \cup e \notin G'[\gamma][H \Delta L] - O$. We claim that $b \cup Q \cup e$ contains some edge from $L - \{b \cup e\}$ or $O$. Since $b \cup Q \cup e \in G'[\gamma]$, there is $e' \in (b, Q, \gamma)$ with $e' \notin H \Delta L$ or there is $e' \in (b, Q, \gamma)$ with $e' \in O$. In the latter case we are done, suppose that the first case applies. Since $e \in G'[\gamma]^{(r-i)}$, we have that $b \cup e$ is a $(3\varepsilon + \gamma', p_B d_B, f - i, r - i)$-regular.

For fixed $b \in B$, a double application of Proposition 5.7 implies that there are at most $(\frac{f}{r})^{f-5r} \gamma n^{f-r}$ $f$-sets that contain $b \cup e$ and some edge from $L - \{b \cup e\}$ or $O$. Thus, we conclude with Claim 4 that $|G'[\gamma]^{(r-i)}(e) \Delta Q'_e| \leq |B| \cdot \frac{1.05(f)}{(f-r)!} \gamma n^{f-r}$. Hence,

$$|G'[\gamma]^{(r-i)}(e)| = |Q'_e| \pm \gamma n_B^{f-r} = (p_B d_B \pm (3\varepsilon + \gamma'))n_B^{f-r},$$

meaning that $G'[\gamma]$ is indeed $(3\varepsilon + \gamma', p_B d_B, f - i, r - i)$-regular.

Next, we claim that $G'[\gamma]$ is $(\xi^r - \gamma^r, f + r - 2i, r - i)$-dense. Consider $e \in G'[\gamma]^{(r-i)}$. We have that $|Q'_e| \geq \xi^r n_B^{f-r}$. Similarly to Claim 4, for every $Q \in \mathcal{Q}_e - G'[\gamma]^{(r-2i)}(e)$ there is some $b \in B$ such that $b \cup Q \cup e$ contains some edge from $L - \{b \cup e\}$ or $O$. Thus, using Proposition 5.7 again (with $f + r - i$ playing the role of $f$), we deduce that

$$|\mathcal{Q}_e - G'[\gamma]^{(r-2i)}(e)| \leq |B| \cdot \frac{(f-r+i) + (f-r+i) f^{-5r}}{(f-r)!} \gamma n^{f-r-i} \leq 2^i \cdot \frac{1.05(f)}{(f-r)!} \gamma n^{f-i},$$

and thus $|G'[\gamma]^{(r-2i)}(e)| \leq (\xi^r - \gamma^r)n_B^{f-r-i}$.

Finally, we claim that $G'[\gamma]$ is $(\xi^r - \gamma^r, f - i, r - i)$-extendable. Let $e \in (\mathcal{Q}_e - \mathcal{Q}_e)$. We have that $|\text{Ext}_{e,G'}| \geq \xi^r n_B^{f-r}$. Let $\text{Ext}_{e,G'}$ contain all $Q \in \text{Ext}_e$ such that $(\mathcal{Q}_e - \mathcal{Q}_e) \setminus \{e\} \subseteq G'[\gamma]$. Suppose that $Q \in \text{Ext}_{e'} \setminus \text{Ext}_{e,G'}$. Then there are $e' \in (\mathcal{Q}_e - \mathcal{Q}_e) \setminus \{e\}$ and $b \in B$ such that $b \cup e' \notin H \Delta L$. On the other hand, we have $b \cup e \in H$ as $Q \in \text{Ext}_e$. Thus, $b \cup e' \in L$. Thus, for all $Q \in \text{Ext}_{e'} \setminus \text{Ext}_{e,G'}$, there is some $b \in B$ such that $b \cup Q \cup e$ contains some edge from $L - \{b \cup e\}$. Proposition 5.7 implies that there are at most $|B| \cdot \frac{(f)}{(f-r)!} \gamma n^{f-r}$ such $Q$. Thus,

$$|\text{Ext}_{e,G'}| \geq |\text{Ext}_{e'}| - 2^i \cdot \frac{(f)}{(f-r)!} \gamma n^{f-r} \geq (\xi^r - \gamma^r)n_B^{f-r}.$$

We conclude that $G'$ is a $(3\varepsilon + \gamma', \xi^r - \gamma^r, f - i, r - i)$-complex, as required. \qed

In particular, the above proposition implies the following.

**Corollary 5.19.** Let $1/n < \varepsilon, \gamma, \xi, p, 1/f$ and $r \in [f - 1]$. Let

$$\xi' := 0.95\xi p^{2r(f-r)} \geq 0.95\xi p^{8f} \text{ and } \gamma' := 1.1 \cdot 2^r \frac{(f-r)}{(f-r)}/\gamma.$$
Suppose that $G$ is an $(\varepsilon, \xi, f, r)$-supercomplex on $n$ vertices and that $H \subseteq G^{(r)}$ is a random subgraph obtained by including every edge of $G^{(r)}$ independently with probability $p$. Then whp the following holds: for all $L \subseteq G^{(r)}$ with $\Delta(L) \leq \gamma n$, $G[H \triangle L]$ is a $(3\varepsilon + \gamma', \xi' - \gamma', f, r)$-supercomplex.

5.5. Rooted Embeddings. We now prove a result (Lemma 5.20) which allows us to find edge-disjoint embeddings of graphs with a prescribed ‘root embedding’. Let $T$ be an $r$-graph and suppose that $X \subseteq V(T)$ is such that $T[X]$ is empty. A root of $(T, X)$ is a set $S \subseteq X$ with $|S| \in [r - 1]$ and $|T(S)| > 0$.

For an $r$-graph $G$, we say that $\Lambda : X \to V(G)$ is a $G$-labelling of $(T,X)$ if $\Lambda$ is injective. Our aim is to embed $T$ into $G$ such that the roots of $(T, X)$ are embedded at their assigned position. More precisely, given a $G$-labelling $\Lambda$ of $(T,X)$, we say that $\phi$ is a $\Lambda$-faithful embedding of $(T, X)$ into $G$ if $\phi$ is an injective homomorphism from $T$ to $G$ with $\phi|_X = \Lambda$. Moreover, for a set $S \subseteq V(G)$ with $|S| \in [r - 1]$, we say that $\Lambda$ roots $S$ if $S \subseteq \text{Im}(\Lambda)$ and $|T(\Lambda^{-1}(S))| > 0$, i.e. if $\Lambda^{-1}(S)$ is a root of $(T, X)$.

The degeneracy of $T$ rooted at $X$ is the smallest $D$ such that there exists an ordering $v_1, \ldots, v_k$ of the vertices of $V(T) \setminus X$ such that for every $\ell \in [k]$, we have

$$|T[X \cup \{v_1, \ldots, v_{\ell}\}](v_{\ell})| \leq D,$$

i.e. every vertex is contained in at most $D$ edges which lie to the left of that vertex in the ordering.

We need to be able to embed many copies of $(T, X)$ simultaneously (with different labellings) into a given host graph $G$ such that the different embeddings are edge-disjoint. In fact, we need a slightly stronger disjointness criterion. Ideally, we would like to have that two distinct embeddings intersect in less than $\varepsilon$ vertices. However, this is in general not possible because of the desired rooting. We therefore introduce the following concept of a hull. We will ensure that the hulls are edge-disjoint, which will be sufficient for our purposes. Given $(T, X)$ as above, the hull of $(T, X)$ is the $r$-graph $T'$ on $V(T)$ with $e \in T'$ if and only if $e \cap X = \emptyset$ or $e \cap X$ is a root of $(T, X)$.

Note that $T \subseteq T' \subseteq K^{(r)}_{V(T)} - K^{(r)}_X$, where $K^{(r)}_Z$ denotes the complete $r$-graph with vertex set $Z$. Moreover, the roots of $(T', X)$ are precisely the roots of $(T, X)$.

Lemma 5.20. Let $1/n \ll \gamma \ll \xi, 1/t, 1/D$ and $r \in [t]$. Suppose that $\alpha \in (0,1]$ is an arbitrary scalar (which might depend on $n$) and let $m \leq \alpha \gamma n^r$ be an integer. For every $j \in [m]$, let $T_j$ be an $r$-graph on at most $t$ vertices and $X_j \subseteq V(T_j)$ such that $T_j[X_j]$ is empty and $T_j$ has degeneracy at most $D$ rooted at $X_j$. Let $G$ be an $r$-graph on $n$ vertices such that for all $A \subseteq \binom{V(G)}{r-1}$ with $|A| \leq D$, we have $|\bigcap_{S \in A} G(S)| \geq \xi n$. Let $O$ be an $(r+1)$-graph on $V(G)$ with $\Delta(O) \leq \gamma n$. For every $j \in [m]$, let $\Lambda_j$ be a $G$-labelling of $(T_j, X_j)$. Suppose that for all $S \subseteq V(G)$ with $|S| \in [r - 1]$, we have that

$$(5.2) \quad |\{j \in [m] : \Lambda_j \text{ roots } S\}| \leq \alpha \gamma n^{r-|S|} - 1.$$

Then for every $j \in [m]$, there exists a $\Lambda_j$-faithful embedding $\phi_j$ of $(T_j, X_j)$ into $G$ such that the following hold:

(i) for all distinct $j, j' \in [m]$, the hulls of $(\phi_j(T_j), \text{Im}(\Lambda_j))$ and $(\phi_{j'}(T_{j'}), \text{Im}(\Lambda_{j'}))$ are edge-disjoint;

(ii) for all $j \in [m]$ and $e \subseteq O$ with $e \subseteq \text{Im}(\phi_j)$, we have $e \subseteq \text{Im}(\Lambda_j)$;

(iii) $\Delta(\bigcup_{j \in [m]} \phi_j(T_j)) \leq \alpha \gamma (2^r - 1)n$.

Note that (i) implies that $\phi_1(T_1), \ldots, \phi_m(T_m)$ are edge-disjoint. We also remark that the $T_j$ do not have to be distinct; in fact, they could all be copies of a single $r$-graph $T$.

Proof. For $j \in [m]$ and a set $S \subseteq V(G)$ with $|S| \in [r - 1]$, let

$$\text{root}(S, j) := |\{j' \in [j] : \Lambda_{j'} \text{ roots } S\}|.$$

We will define $\phi_1, \ldots, \phi_m$ successively. Once $\phi_j$ is defined, we let $K_j$ denote the hull of $(\phi_j(T_j), \text{Im}(\Lambda_j))$. Note that $\phi_j(T_j) \subseteq K_j$ and that $K_j$ is not necessarily a subgraph of $G$.

Suppose that for some $j \in [m]$, we have already defined $\phi_1, \ldots, \phi_{j-1}$ such that $K_1, \ldots, K_{j-1}$ are edge-disjoint, (ii) holds for all $j' \in [j - 1]$, and the following holds for $G_j := \bigcup_{j' \in [j-1]} K_{j'}$, all
i ∈ [r − 1] and all S ∈ \((V(G))_i\):

\[
|G_j(S)| \leq \alpha \gamma^{(2-r)} n^{r-i} + (\text{root}(S, j-1) + 1)2^i.
\]

Note that (5.3) together with (5.2) implies that for all i ∈ [r − 1] and all S ∈ \((V(G))_i\), we have

\[
|G_j(S)| \leq 2\alpha \gamma^{(2-r)} n^{r-i}.
\]

We will now define a \(\Lambda_j\)-faithful embedding \(\phi_j\) of \((T_j, X_j)\) into \(G\) such that \(K_j\) is edge-disjoint from \(G_j\), (ii) holds for \(j\), and (5.3) holds with \(j\) replaced by \(j + 1\). For \(i \in [r − 1]\), define \(BAD_i := \{S \in (V(G))_i : |G_j(S)| \geq \alpha \gamma^{(2-r)} n^{r-i}\}\). We view \(BAD_i\) as an \(i\)-graph. We claim that for all \(i \in [r − 1]\),

\[
\Delta(BAD_i) \leq \gamma^{(2-r)} n.
\]

Consider \(i \in [r − 1]\) and suppose that there exists some \(S \in (V(G))_i\) such that \(|BAD_i(S)| > \gamma^{(2-r)} n\).

We then have that

\[
|G_j(S)| = \frac{1}{(r-i+1)} \sum_{v \in V(G) \setminus S} |G_j(S \cup \{v\})| \geq r^{-1} \sum_{v \in BAD_i(S)} |G_j(S \cup \{v\})|
\]

\[
\geq r^{-1}|BAD_i(S)|\alpha \gamma^{(2-r)} n^{r-i} \geq r^{-1} \gamma^{(2-r)} n \alpha \gamma^{(2-r)} n^{r-i} = r^{-1} \alpha \gamma^{(2-r+2)} n^{r-(i-1)}.
\]

This contradicts (5.4) if \(i - 1 > 0\) since \(2^{-r} + 2^{-i} < 2^{-(i-1)}\). If \(i = 1\), then \(S = \emptyset\) and we have \(|G_j| \geq r^{-1} \alpha \gamma^{(2-r+2)} n^{r}\), which is also a contradiction since \(|G_j| \leq m(i) \leq \left(\begin{array}{c} t \\ r \end{array}\right) \alpha \gamma n^r\) and \(2^{-r} + 2^{-1} < 1\) (as \(r \geq 2\) if \(i \in [r−1]\)). This proves (5.5).

We now embed the vertices of \(T_j\) such that the obtained embedding \(\phi_j\) is \(\Lambda_j\)-faithful. First, embed every vertex from \(X_j\) at its assigned position. Since \(T_j\) has degeneracy at most \(D\) rooted at \(X_j\), there exists an ordering \(v_1, \ldots, v_k\) of the vertices of \(V(T_j) \setminus X_j\) such that for every \(\ell \in [k]\),

\[
|T_j[X_j \cup \{v_1, \ldots, v_\ell\}]| \leq D.
\]

Suppose that for some \(\ell \in [k]\), we have already embedded \(v_1, \ldots, v_{\ell-1}\). We now want to define \(\phi_j(v_\ell)\). Let \(U := \{\phi_j(v) : v \in X_j \cup \{v_1, \ldots, v_{\ell-1}\}\}\) be the set of vertices which have already been used as images for \(\phi_j\). Let \(A\) contain all \((r-1)\)-subsets \(S\) of \(U\) such that \(\phi_j^{-1}(S) \cup \{v_\ell\} \in T_j\). We need to choose \(\phi_j(v_\ell)\) from the set \((\bigcap_{S \in A} G(S)) \setminus U\) in order to complete \(\phi_j\) to an injective homomorphism from \(T_j\) to \(G\). By (5.6), we have \(|A| \leq D\). Thus, by assumption, \(|\bigcap_{S \in A} G(S)| \geq \xi n\).

For \(i \in [r − 1]\), let \(O_i\) consist of all vertices \(x \in V(G)\) such that there exists some \(S \in \binom{V(G)}{t-1}\) such that \(S \cup \{x\} \in BAD_i\) (so \(BAD_i = \binom{O_i}{t-1}\)). We have

\[
|O_i| \leq \left(\frac{|U|}{i-1}\right) \Delta(BAD_i) \leq \left(\frac{t}{i-1}\right) \gamma^{(2-r)} n.
\]

Let \(O_r\) consist of all vertices \(x \in V(G)\) such that \(S \cup \{x\} \in G_j\) for some \(S \in \binom{V(G)}{t-1}\). By (5.4), we have that \(|O_r| \leq \left(\frac{|U|}{t-1}\right) \Delta(G_j) \leq \left(\frac{t}{t-1}\right) 2\alpha \gamma^{(2-r-1)} n \leq \left(\frac{t}{r-1}\right) \gamma^{(2-r)} n\). Finally, let \(O_{r+1}\) be the set of all vertices \(x \in V(G)\) such that there exists some \(S \in \binom{V(G)}{r}\) such that \(S \cup \{x\} \in O\). By assumption, we have \(|O_{r+1}| \leq \left(\frac{|U|}{r}\right) \Delta(O) \leq \left(\frac{t}{r}\right) \gamma n\).

Crucially, we have

\[
|\bigcap_{S \in A} G(S)| − |U| − \sum_{i=1}^{r+1}|O_i| \geq \xi n − t − 2\gamma^{(2-r)} n > 0.
\]

Thus, there exists a vertex \(x \in V(G)\) such that \(x \notin U \cup O_1 \cup \cdots \cup O_{r+1}\) and \(S \cup \{x\} \in G\) for all \(S \in A\). Define \(\phi_j(v_\ell) := x\).

Continuing in this way until \(\phi_j\) is defined for every \(v \in V(T_j)\) yields an injective homomorphism from \(T_j\) to \(G\). By definition of \(O_{r+1}\), (ii) holds for \(j\). Moreover, by definition of \(O_r\), \(K_j\) is edge-disjoint from \(G_j\). It remains to show that (5.3) holds with \(j\) replaced by \(j + 1\). Let \(i \in [r − 1]\)
and \( S \in \binom{V(G)}{1} \). If \( S \notin \text{BAD}_t \), then we have \(|G_j+1(S)| \leq |G_j(S)| + \binom{n-r}{i} \leq \alpha \gamma^{(2-i)n-r-i} + 2^t\), so (5.3) holds. Now, assume that \( S \in \text{BAD}_t \). If \( S \subseteq \text{Im}(\Lambda_j) \) and \(|T_j(\Lambda_j^{-1}(S))| > 0\), then

\[
\text{root}(S,j) = \text{root}(S,j-1) + 1 \quad \text{and thus} \quad |G_{j+1}(S)| \leq |G_j(S)| + \binom{n-r}{i} \leq \alpha \gamma^{(2-i)n-r-i} + (\text{root}(S,j-1) + 1)2^t + \binom{n-r}{i} \leq \alpha \gamma^{(2-i)n-r-i} + (\text{root}(S,j) + 1)2^t \quad \text{and (5.3) holds.}
\]

Suppose next that \( S \not\subseteq \text{Im}(\Lambda_j) \). We claim that \( S \not\subseteq V(\phi_j(T_j)) \). Suppose, for a contradiction, that \( S \subseteq V(\phi_j(T_j)) \). Let 

\[
\ell := \max\{\ell' \in [k] : \phi_j(v_{\ell'}) \in S\}
\]

(Note that the maximum exists since \((S \cap V(\phi_j(T_j))) \cap \text{Im}(\Lambda_j)\) is not empty.) Hence, \( x := \phi_j(v_{\ell'}) \in S \). Recall that when we defined \( \phi_j(v_{\ell'}) \), \( \phi_j(v) \) had already been defined for all \( v \in X_j \) \cup \{v_1, \ldots, v_{r-1}\} \) and hence \( S \not\subseteq \{x\} \subseteq U \). But since \( S \in \text{BAD}_t \), we have \( x \in O_i \), in contradiction to \( x = \phi_j(v_{\ell'}) \). Thus, \( S \not\subseteq V(\phi_j(T_j)) = V(K_j) \), which clearly implies that \(|G_{j+1}(S)| = |G_j(S)|\) and (5.3) holds. The last remaining case is if \( S \subseteq \text{Im}(\Lambda_j) \) but \(|T_j(\Lambda_j^{-1}(S))| = 0\). But then \( S \) is not a root of \( (\phi_j(T_j), \text{Im}(\Lambda_j)) \) and thus not a root of \( (K_j, \text{Im}(\Lambda_j)) \). Hence \(|K_j(S)| = 0\) and therefore \(|G_{j+1}(S)| = |G_j(S)|\) as well.

Finally, if \( j = m \), then the fact that (5.3) holds with \( j \) replaced by \( j + 1 \) together with (5.2) implies that \( \Delta(|\bigcup_{e \in [m]} \phi_j(T_j)|) \leq 2\alpha \gamma^{(2-(r-1))n} \leq \alpha \gamma^{(2-r)n} \). \( \square \)

### 6. Nibbles, Boosting and Greedy Covers

#### 6.1. The nibble

There are numerous results based on the Rödl nibble which guarantee the existence of an almost perfect matching in a near regular hypergraph with small codegrees. Our application of this is as follows: Let \( G \) be a complex. Define the auxiliary \((\ell)\)-graph \( H \) with \( V(H) = E(G(\ell)) \) and \( E(H) = \{\{Q\} : Q \in G(\ell)\} \). Note that for every \( e \in V(H) \), \(|H(e)| = |G(\ell)(e)|\). Thus, if \( G \) is \((\varepsilon, d, f, r)\)-regular, then every vertex of \( H \) has degree \((d \pm \varepsilon)n^{r-1}\). Moreover, for two vertices \( e, e' \in V(H) \), we have \(|H(e, e')| \leq n^{f-r-1}, \) thus \( \Delta_2(H) \leq n^{f-r-1} \). Standard nibble theorems would in this setting imply the existence of an almost perfect matching in \( H \), which translates into a \( K^{(r)} \)-packing in \( G \) that covers all but \( o(n^r) \)-edges. We need a stronger result in the sense that we want the leftover \( r \)-edges to induce a \( r \)-graph with small maximum degree. Alon and Yuster [2] observed that one can use a result of Pippenger and Spencer [37] (on the chromatic index of uniform hypergraphs) to show that a near regular hypergraph with small codegrees has an almost perfect matching which is ‘well-behaved’. The following is an immediate consequence of Theorem 1.2 in [2] (applied to the auxiliary hypergraph \( H \) above).

**Theorem 6.1 ([2]).** Let \( 1/n \ll \varepsilon \ll \gamma, d, 1/f \) and \( r \in [f-1] \). Suppose that \( G \) is an \((\varepsilon, d, f, r)\)-regular complex on \( n \) vertices. Then \( G \) contains a \( K^{(r)} \)-packing \( \mathcal{K} \) such that \( \Delta(G^{(r)} - \mathcal{K}^{(r)}) \leq \gamma n \).

#### 6.2. The Boost lemma

We will now state and prove the ‘Boost lemma’, which ‘boosts’ the regularity of a complex by restricting to a suitable set \( Y \) of \( f \)-sets. It will help us to keep the error terms under control during the iteration process and also helps us to obtain meaningful resilience and minimum degree bounds.

The proof is based on the following ‘edge-gadgets’, which were used in [6] to obtain fractional \( K^{(r)}_f \)-decompositions of \( r \)-graphs with high minimum degree. These edge-gadgets allow us to locally adjust a given weighting of \( f \)-sets so that this changes the total weight at only one \( r \)-set.

**Proposition 6.2** (see [6, Proposition 3.3]). Let \( f > r \geq 1 \) and let \( e \) and \( J \) be disjoint sets with \(|e| = r \) and \(|J| = f \). Let \( G \) be the complete complex on \( e \cup J \). There exists a function \( \psi : G^{(f)} \to \mathbb{R} \) such that

\[
\begin{align*}
(i) & \quad \text{for all } e' \in G^{(r)}, \sum_{Q \in G^{(f)}_J(e')} \psi(Q \cup e') = \begin{cases} 1, & e' = e, \\ 0, & e' \neq e; \end{cases} \\
(ii) & \quad \text{for all } Q \in G^{(f)}_J, |\psi(Q)| \leq \frac{2^{r-1}(r-j)!}{(f+j)!}, \text{ where } j := |e \cap Q|. 
\end{align*}
\]

We use these gadgets as follows. We start off with a complex that is \((\varepsilon, d, f, r)\)-regular for some reasonable \( \varepsilon \) and consider a uniform weighting of all \( f \)-sets. We then use the edge-gadgets to shift weights until we have a ‘fractional \( K^{(r)}_f \)-equicovering’ in the sense that the weight of each edge...
is exactly \( d' n^{f-r} \) for some suitable \( d' \). We then use this fractional equicovering as an input for a probabilistic argument.

**Lemma 6.3** (Boost lemma). Let \( 1/n \ll \varepsilon, \xi, 1/f \) and \( r \in [f-1] \) such that \( 2(2\sqrt{e})^r \varepsilon \leq \xi \).

Let \( \xi' := 0.9(1/4)^{(f+r)/r} \xi \). Suppose that \( G \) is a complex on \( n \) vertices and that \( G \) is \( (\varepsilon, d, f, r) \)-regular for some \( d \geq \xi \) and \((\xi, f + r, r)\)-dense. Then there exists \( Y \subseteq G^{(f)} \) such that \( G[Y] \) is \((n-(f-r)/2.01, d/2, f, r)\)-regular and \((\xi', f + r, r)\)-dense.

**Proof.** Let \( d' := d/2 \). Assume that \( \psi: G^{(f)} \to [0, 1] \) is a function such that for every \( e \in G^{(r)} \),

\[
\sum_{Q' \in G^{(f)}(e)} \psi(Q' \cup e) = d' n^{f-r},
\]

and \( 1/4 \leq \psi(Q) \leq 1 \) for all \( Q \in G^{(f)} \). We can then choose \( Y \subseteq G^{(f)} \) by including every \( Q \in G^{(f)} \) with probability \( \psi(Q) \) independently. We then have for every \( e \in G^{(r)} \) and \( Q \in G^{(f+r)}(e) \), we have that

\[
P(Q \in G[Y]^{(f+r)}(e)) = \prod_{Q' \in \psi(Q,e)} \psi(Q') \geq (1/4)^{(f+r)/r}.
\]

Therefore, \( E[G[Y]^{(f+r)}(e)] \geq (1/4)^{(f+r)/r} \xi n^f \), and using Corollary 5.14 we deduce that

\[
P(|G[Y]^{(f+r)}(e)| \leq 0.9(1/4)^{(f+r)/r} \xi n^f) \leq e^{-n^{1/6}}.
\]

Thus, whp \( G[Y] \) is \((0.9(1/4)^{(f+r)/r} \xi, f + r, r)\)-dense.

It remains to show that \( \psi \) exists. For every \( e \in G^{(r)} \), define

\[
c_e := \frac{d' n^{f-r} - 0.5 |G^{(f)}(e)|}{|G^{(f+r)}(e)|}.
\]

Observe that \( |c_e| \leq \frac{en^{f-r}}{2e n^r} = \frac{\varepsilon}{2} n^{-r} \) for all \( e \in G^{(r)} \).

By Proposition 6.2, for every \( e \in G^{(r)} \) and \( J \in G^{(f+r)}(e) \), there exists a function \( \psi_{e,J}: G^{(f)} \to \mathbb{R} \) such that

(i) \( \psi_{e,J}(Q) = 0 \) for all \( Q \not\subseteq e \cup J \);

(ii) for all \( e' \in G^{(r)} \), \( \sum_{Q' \in G^{(f)}(e')} \psi_{e,J}(Q' \cup e') = \begin{cases} 1, & e' = e, \\ 0, & e' \neq e; \end{cases} \)

(iii) for all \( Q \in G^{(f)} \), \( |\psi_{e,J}(Q)| \leq 2^{\varepsilon^{-j} (j-1)!} \), where \( j := |e \cap Q| \).

We now define \( \psi: G^{(f)} \to [0, 1] \) as

\[
\psi := 1/2 + \sum_{e \in G^{(r)}} c_e \sum_{J \in G^{(f+r)}(e)} \psi_{e,J}.
\]

For every \( e \in G^{(r)} \), we have

\[
\sum_{Q' \in G^{(f)}(e)} \psi(Q' \cup e) = 0.5 |G^{(f)}(e)| + \sum_{e' \in G^{(r)}} c_{e'} \sum_{J \in G^{(f+r)}(e') \cap G^{(f)}(e)} \psi_{e',J}(Q' \cup e)
\]

\[
\leq 0.5 |G^{(f)}(e)| + c_e |G^{(f+r)}(e)| = d' n^{f-r},
\]
Our strategy to prove Lemma 6.5 is thus as follows: We apply Lemma 6.4 to out, the leftover packing \( \psi(e) \) for which \( e \in G^{(r)} \), \( J \in G^{(f+r)}(e), Q \subseteq e \cup J \) and \( |Q \cap e| = j \). Hence,

\[
|\psi(Q) - 1/2| = \left| \sum_{e \in G^{(r)}} c_e \sum_{J \in G^{(f+r)}(e)} \psi_e(J)(Q) \right| \leq \sum_{e \in G^{(r)}, J \in G^{(f+r)}(e)} c_e|\psi_e(J)(Q)| \leq \sum_{j=0}^r \binom{n}{r} \frac{f}{j!} \frac{r-j}{2^j} \frac{2^r}{2^{j-r}} \frac{(f-r+j)!}{(r-j)!} \leq \frac{2^{r-1} \xi}{\xi} \sum_{j=0}^r \frac{(f/2)^j}{j!} \leq 1/4,
\]

implying that \( 1/4 \leq \psi(Q) \leq 3/4 \) for all \( Q \in G^{(f)} \), as needed.

**Proof of Lemma 4.4.** Let \( G \) be an \( (\varepsilon, \xi, f, r) \)-complex on \( n \) vertices. By definition, there exists \( Y \subseteq G^{(f)} \) such that \( G[Y] \) is \( (\varepsilon, d, f, r) \)-regular for some \( d \geq \xi \), \( (\xi, f + r, r) \)-dense and \( (\xi, f, r) \)-extendable. We can thus apply the Boost lemma (Lemma 6.3) with \( G[Y] \) playing the role of \( G \). This yields \( Y' \subseteq Y \) such that \( G[Y'] \) is \((n^{-1/3}, d/2, f, r)\)-regular and \((\xi, f + r, r)\)-dense. Since \( G[Y']^{(r)} = G[Y]^{(r)}, \) \( G[Y']^{(r)} \) is also \((\xi, f, r)\)-extendable. Thus, \( G \) is an \((n^{-1/3}, \xi, f, r)\)-complex.

Suppose now that \( G \) is an \((\varepsilon, \xi, f, r)\)-supercomplex. Let \( i \in [r] \) and \( B \subseteq G^{(i)} \) with \( 1 \leq |B| \leq 2^i \). We have that \( G_B := \bigcap_{b \in B} G(b) \) is an \((\varepsilon, \xi, f - i, r - i)\)-complex. If \( i < r \), we deduce by the above that \( G_B \) is an \((n^{-1/3}, \xi, f - i, r - i)\)-complex. If \( i = r \), this also holds by Fact 4.2.

Lemma 6.3 together with Theorem 6.1 immediately implies the following ‘Boosted nibble lemma’. In contrast to Theorem 6.1, we do not need to require \( \varepsilon \ll \gamma \) here.

**Lemma 6.4 (Boosted nibble lemma).** Let \( 1/n \ll \gamma, \varepsilon \ll \xi, 1/f \) and \( r \in [f - 1] \). Let \( G \) be a complex on \( n \) vertices such that \( G[Y] \) is \((\varepsilon, d, f, r)\)-regular for some \( d \geq \xi \) and \((\xi, f + r, r)\)-dense and \((\xi, f, r)\)-extendable. Then \( G \) contains a \((\frac{1}{2}, \frac{1}{3})\)-packing \( K \) such that \( \Delta(G^{(r)} - K^{(r)}) \leq \gamma n \).

### 6.3 Approximate F-decompositions

We now prove an \( F \)-nibble lemma which allows us to find \( \kappa \)-well separated approximate \( F \)-decompositions in supercomplexes. Whenever we need an approximate decomposition in the proof of Theorem 4.7, we will obtain it via Lemma 6.5.

**Lemma 6.5 (F-nibble lemma).** Let \( 1/n \ll 1/\kappa, \varepsilon \ll \xi, 1/f \) and \( r \in [f - 1] \). Let \( G \) be an \( r \)-graph on \( f \) vertices. Let \( G \) be a complex on \( n \) vertices such that \( G \) is \((\varepsilon, d, f, r)\)-regular and \((\xi, f + r, r)\)-dense for some \( d \geq \xi \). Then \( G \) contains a \( \kappa \)-well separated \( F \)-packing \( \mathcal{F} \) such that \( \Delta(G^{(r)} - \mathcal{F}^{(r)}) \leq \gamma n \).

Let \( F \) be an \( r \)-graph on \( f \) vertices. Given a collection \( K \) of edge-disjoint copies of \( K^{(r)} \), we define the \( \kappa \)-random \( F \)-packing \( \mathcal{F} \) as follows: For every \( K \in \mathcal{K} \), choose a random bijection from \( V(F) \) to \( V(K) \) and let \( F_K \) be a copy of \( F \) on \( V(K) \) embedded by this bijection. Let \( \mathcal{F} := \{ F_K : K \in \mathcal{K} \} \).

Clearly, if \( K \) is a \( K^{(r)} \)-decomposition of a complex \( G \), then the \( \kappa \)-random \( F \)-packing \( \mathcal{F} \) is a 1-well separated \( F \)-packing in \( G \). Moreover, writing \( p := 1 - |F|/|J| \), we have \( |\mathcal{F}(r)| = |F||K| = |F||G^{(r)}|/|J| = (1 - p)|G^{(r)}| \), and for every \( e \in G^{(r)} \), we have \( \mathbb{P}(e \in G^{(r)} - \mathcal{F}^{(r)}) = p \). As it turns out, the leftover \( G^{(r)} - \mathcal{F}^{(r)} \) behaves essentially like a \( p \)-random subgraph of \( G^{(r)} \) (cf. Lemma 6.6). Our strategy to prove Lemma 6.5 is thus as follows: We apply Lemma 6.4 to \( G \) to obtain a \( K^{(r)} \)-packing \( K_1 \) such that \( \Delta(G^{(r)} - K_1^{(r)}) \leq \gamma n \). The leftover here is negligible, so assume for the moment that \( K_1 \) is a \( K^{(r)} \)-decomposition. We then choose a \( K_1 \)-random \( F \)-packing \( \mathcal{F}_1 \) in \( G \) and continue the process with \( G - \mathcal{F}_1^{(r)} \). In each step, the leftover decreases by a factor of \( p \). Thus after \( \log_p \gamma \) steps, the leftover will have maximum degree at most \( \gamma n \).

**Lemma 6.6.** Let \( 1/n \ll \varepsilon \ll \xi, 1/f \) and \( r \in [f - 1] \). Let \( F \) be an \( r \)-graph on \( f \)-vertices with \( p := 1 - |F|/|J| \in (0, 1) \). Let \( G \) be an \((\varepsilon, d, f, r)\)-regular and \((\xi, f + r, r)\)-dense complex on \( n \)
vertices for some \( d \geq \xi \). Suppose that \( K \) is a \( K^{(r)}_f \)-decomposition of \( G \). Let \( F \) be the \( K \)-random \( F \)-packing in \( G \). Then whp the following hold for \( G' := G - K^{(r+1)} - F^{(r)} \).

(i) \( G' \) is \((2\epsilon, p^{(f)} d, f, r)\)-regular;
(ii) \( G' \) is \((0.9p^{(f)} r^{-1}\xi, f + r, r)\)-dense;
(iii) \( \Delta(G'(r)) \leq 1.1p\Delta(G'(r)) \).

**Proof.** For \( e \in G'(r) \), let \( K_e \) be the unique element of \( K^{(f)}_r \) with \( e \subseteq K_e \). Let \( G_{\text{ind}} := G - K^{(r+1)} \). \( G'(r) \) is a random subgraph of \( G_{\text{ind}} \), where for any \( I \subseteq G'(r) \), the events \( \{e \in G'(r)\} \) are independent if the sets \( \{K_e\} \) are distinct. Since \( \Delta(K^{(r+1)}) \leq f - r \), Proposition 5.9 implies that \( G_{\text{ind}} \) is \((1.1c, d, f, r)\)-regular and \((\xi - \epsilon, f + r, r)\)-dense.

For \( e \in G'(r) \), let \( Q_e := G_{\text{ind}}(e) \) and \( \tilde{Q}_e := G_{\text{ind}}'(e) \). Thus, \(|Q_e| = (d + 1.1c)n^{f-r} \) and \(|\tilde{Q}_e| \geq 0.95\xi n^r \). Let \( Q'_e \) be the random subgraph of \( Q_e \) consisting of all \( Q \subseteq Q_e \) with \( \{Q, e\} \subseteq G'(r) \). Similarly, let \( \tilde{Q}'_e \) be the random subgraph of \( \tilde{Q}_e \) consisting of all \( Q \subseteq \tilde{Q}_e \) with \( \{\tilde{Q}, e\} \subseteq G'(r) \). Note that if \( e \in G'(r) \), then \( Q'_e = G_{\text{ind}}'(e) \). Moreover, note that by definition of \( G_{\text{ind}} \), we have

\[
|\{e \cup Q \cap K| \leq r \text{ for all } Q \subseteq Q_e, K \in K.
\]

Consider \( Q \subseteq Q_e \). By (6.1), the \( K_e \) with \( e' \in (Q_e \setminus \{e\}) \) are all distinct, hence we have

\[P(Q \in Q'_e) = p^{(f)} n^{f-r-1}.\]

Thus, \(|Q'_e| = p^{(f)} n^{f-r-1}|Q_e|\).

Define an auxiliary graph \( A_e \) on vertex set \( Q_e \) where \( QQ' \in A_e \) if and only if there exists \( K \in K^{(f)}_r \{K_e\} \) such that \(|e \cup Q \cap K = r \) and \(|e \cup Q \cap K = r \). Using (6.1), it is easy to see that if \( Y \) is an independent set in \( A_e \), then the events \( \{Q \subseteq Q'_e\}_{Q \in Y} \) are independent.

**Claim 1:** \( Q_e \) can be partitioned into \( 2p^{(f)} n^{f-r-1} \) independent sets in \( A_e \).

**Proof of claim:** It is sufficient to prove that \( \Delta(A_e) \leq (f-1)^2 n^{f-r-1} \). Fix \( Q \subseteq V(A_e) \). There are \( (f-1) \) \(-r\)-subsets \( e' \cup Q \) other than \( e \). For each of these, \( K_{e'} \) is the unique \( K \in K^{(f)}_r \{K_e\} \) such that \( e' \subseteq K \). Each choice of \( K_{e'} \) has \((f-1) \) \(-r\)-subsets \( e'' \). If we want \( e \cup Q \)' to contain \( e'' \), then since \( e'' \neq e \), we have \(|e \cup e''| \geq r + 1 \) and thus there are at most \( n^{f-r-1} \) possibilities for \( e'' \). By Lemma 5.12, we thus have \( P(|Q'_e| \neq (1 \pm n^{-1/5})p|Q_e|) \leq n^{-1/6} \). We conclude that with probability at least \( 1 - n^{-1/6} \) we have \(|Q'_e| = p^{(f)} n^{f-r-1} \). Together with a union bound, this implies that whp \( G' \) is \((2\epsilon, p^{(f)} d, f, r)\)-regular, which proves (i).

A similar argument shows that whp \( G' \) is \((0.9p^{(f)} r^{-1}\xi, f + r, r)\)-dense. To prove (iii), let \( S \subseteq \binom{V(G)}{f} \). Clearly, we have \(|G'(r)(S)| = p|G'(r)(S)| \). If \(|G'(r)(S)| = 0 \), then we clearly have \(|G'(r)(S)| \leq 1.1p\Delta(G'(r)) \), so assume that \( S \subseteq e \in G'(r) \). Since \( e \) is contained in at least \( 0.5\xi n^{f-r} \)-sets in \( G' \), and every \(-r\)-set \( e' \neq e \) is contained in a most \( n^{f-r+1} \) of these, we can deduce that \(|G'(r)(S)| \geq 0.5\xi n^{f-r} \). Define the auxiliary graph \( A_S \) with vertex set \( G'(r)(S) \) such that \( e_1 e_2 \in A_S \) if and only if \( K_{S[1]} = K_{S[2]} \). Again, we have \( \Delta(A_S) \leq f - r \) and whp \( G'(r)(S) \) can be partitioned into \( f - r + 1 \) sets which are independent in \( A_S \). By Lemma 5.12, we thus have \( P(|G'(r)(S)| \neq (1 \pm n^{-1/5})p|G'(r)(S)|) \leq n^{-1/6} \). Using a union bound, we conclude that whp \( \Delta(G'(r)) \leq 1.1p\Delta(G'(r)) \).

**Proof of Lemma 6.5.** Let \( p := 1 - |F|/\binom{f}{r} \). If \( F = K^{(r)}_f \), then we are done by Lemma 6.4. We may thus assume that \( p \in (0, 1) \). Choose \( \epsilon' > 0 \) such that \( 1/n \ll \epsilon' \ll 1/\kappa \ll \gamma, \epsilon \ll p, 1 - p, \xi, 1/f \). We will now repeatedly apply Lemma 6.4. More precisely, let \( \xi_0 := 0.9(1/4)^{1/5} \xi \) and define \( \xi_j := (0.5p^{j} r^{-1}) \xi_0 \) for \( j \geq 1 \). For every \( j \in [\kappa] \), we will find \( F \) and \( G \) such that the following hold:

(a) \( F_{j} \) is a \( \xi_{j} \)-well separated \( F \)-packing in \( G \) and \( G_{j} \subseteq G - F_{j}^{(r)} \);
(b) \( \Delta(L_{j}) \leq j \xi' n \), where \( L_{j} := G^{(r)} - F_{j}^{(r)} - G_{j}^{(r)} \);
(c) \( G_{j} \) is \((2^{r+1})j^{1/5}, d, f, r)\)-regular and \((\xi_{j}, f + r, r)\)-dense for some \( d_{j} \geq \xi_{j} \);
(d) \( F^{(r)}_j \) and \( G_j \) are \((r + 1)\)-disjoint;
(e) \( \Delta(G_j^{(r)}) \leq (1.1)p^3n \).

First, apply Lemma 6.3 to \( G \) in order to find \( Y \subseteq G^{(r)} \) such that \( G_0 := G[Y] \) is \((\varepsilon', d/2, f, r)\)-regular and \((\xi_0, f + r, r)\)-dense. Hence, \((a)_0-\)\( (e)_0 \) hold with \( F_0 := \emptyset \). Also note that \( F_\kappa \) will be a \( \kappa \)-well separated \( F \)-packing in \( G \) and \( \Delta(G^{(r)} - F^{(r)}_\kappa) \leq \Delta(L_\kappa) + \Delta(G^{(r)}_\kappa) \leq \kappa \varepsilon'n + (1.1)p^3n \leq \gamma n \), so we can take \( F := F_\kappa \).

Now, assume that for some \( j \in [n] \), we have found \( F_{j-1} \) and \( G_{j-1} \) and now need to find \( F_j \) and \( G_j \). By \((c)_{j-1} \), \( G_{j-1} \) is \((\sqrt{\varepsilon'}, d_{j-1}, f, r)\)-regular and \((\xi_{j-1}, f + r, r)\)-dense for some \( d_{j-1} \geq \xi_{j-1} \). Thus, we can apply Lemma 6.4 to obtain a \( K^{(r)}_j \)-packing \( K_j \) in \( G_{j-1} \) such that \( \Delta(L'_j) \leq \varepsilon'n \), where \( L'_j := G^{(r)}_{j-1} - K^{(r)}_j \). Let \( G'_j := G_{j-1} - L'_j \). Clearly, \( K_j \) is a \( K^{(r)}_j \)-decomposition of \( G'_j \). Moreover, by \((c)_{j-1} \) and Proposition 5.9 we have that \( G'_j \) is \((2^{(r+1)(j-1)+r}\varepsilon', d_{j-1}, f, r)\)-regular and \((0.9\xi_{j-1}, f + r, r)\)-dense. By Lemma 6.6, there exists a \( 1 \)-well separated \( F \)-packing \( F'_j \) in \( G'_j \) such that the following hold for \( G_j := G'_j - F^{(r)}_j - K^{(r)}_j \)

\( i \) \( G_j \) is \((2^{(r+1)(j-1)+r+1}\varepsilon', p^{(1)}_{j-1}d_{j-1}, f, r)\)-regular;
\( ii \) \( G_j \) is \((0.81p^{(1)}_{j-1}\xi_{j-1}, f + r, r)\)-dense;
\( iii \) \( \Delta(G^{(r)}_j) \leq 1.1p\Delta(G^{(r)}_j) \).

Let \( F_j := F_{j-1} \cup F'_j \) and \( L_j := G^{(r)} - F^{(r)}_j - G^{(r)}_j \). Note that \( F^{(r)}_{j-1} \cup F^{(r)}_j = \emptyset \) by \((a)_{j-1} \). Moreover, \( F_{j-1} \) and \( F_j \) are \((r + 1)\)-disjoint by \((d)_{j-1} \). Thus, \( F_j \) is \((j-1+1)\)-well separated by Fact 5.4(ii). Moreover, using \((a)_{j-1} \), we have

\[ G_j \subseteq G_{j-1} - F^{(r)}_j \subseteq G - F^{(r)}_{j-1} - F^{(r)}_j, \]

thus \((a)_j \) holds. Observe that \( L_j \setminus L_{j-1} \subseteq L'_j \). Thus, we clearly have \( \Delta(L_j) \leq \Delta(L_{j-1}) + \Delta(L'_j) \leq j\varepsilon'n \), so \((b)_j \) holds. Moreover, \((c)_j \) follows directly from \( (i) \) and \( (ii) \), and \((e)_j \) follows from \((e)_{j-1} \) and \( (iii) \). To see \((d)_j \), observe that \( F^{(r)}_{j-1} \) and \( G_j \) are \((r + 1)\)-disjoint by \((d)_{j-1} \) and since \( G_j \subseteq G_{j-1} \), and \( F^{(r)}_j \) and \( G_j \) are \((r + 1)\)-disjoint by definition of \( G_j \). Thus, \((a)_{j-1} - (e)_j \) hold and the proof is completed.

\[ \square \]

### 6.4. Greedy coverings and divisibility

The following lemma allows us to extend a given collection of \( r \)-sets into suitable \( r \)-disjoint \( f \)-cliques (see Corollary 6.9). The full strength of Lemma 6.7 will only be needed in Section 8. The proof consists of a sequential random greedy algorithm.

**Lemma 6.7.** Let \( 1/n \ll \gamma \ll \alpha, 1/s, 1/f \) and \( r \in [f-1] \). Let \( G \) be a complex on \( n \) vertices and let \( L \subseteq G^{(r)} \) satisfy \( \Delta(L) \leq \gamma n \). Suppose that \( L \) decomposes into \( L_1, \ldots, L_m \) with \( 1 \leq |L_j| \leq s \). Suppose that for every \( j \in [m] \), we are given some candidate set \( Q_j \subseteq \bigcap_{e \in L_j} G^{(f)}(e) \) with \( |Q_j| \geq cn^{f-r} \). Then there exists \( Q_j \in Q_j \) for each \( j \in [m] \) such that, writing \( K_j := (Q_j \cup L_j)^\leq \), we have that \( K_j \) and \( K_{j'} \) are \( r \)-disjoint for all distinct \( j, j' \in [m] \), and \( \Delta(\bigcup_{j \in [m]} K^{(r)}_j) \leq \sqrt{\gamma}n \).

**Proof.** Let \( t := 0.5\alpha n^{f-r} \) and consider Algorithm 6.8. We claim that with positive probability, Algorithm 6.8 outputs \( K_1, \ldots, K_m \) as desired.

It is enough to ensure that with positive probability, \( \Delta(T_j) \leq sf_\gamma 2^{3/2}n \) for all \( j \in [m] \). Indeed, note that we have \( L_j \cap T_j = \emptyset \) by construction. Hence, if \( \Delta(T_j) \leq sf_\gamma 2^{3/2}n \), then Proposition 5.7 implies that every \( e \in L_j \) is contained in at most \( (\gamma + sf_\gamma 2^{3/2})2^{n^{f-r}} \) \( f \)-sets of \( V(G) \) that also contain an edge of \( T_j \cup (L - L_j) \). Thus, there are at most \( s(\gamma + sf_\gamma 2^{3/2})2^{n^{f-r}} \leq 0.5\alpha n^{1-r} \) candidates \( Q \in Q_j \) such that \( (Q \cup L_j)^\leq \) contains some edge from \( T_j \cup (L - L_j) \). Hence, \( |Q_j| \geq |Q_j| - 0.5\alpha n^{f-r} \geq |Q_j| - 0.5\alpha n^{f-r} \geq t \), so the algorithm succeeds in round \( j \).

For every \((r-1)\)-set \( S \subseteq V(G) \) and \( j \in [m] \), let \( Y^j \) be the indicator variable of the event that \( S \) is covered by \( K_j \).
Algorithm 6.8

for \( j \) from 1 to \( m \) do
  define the \( r \)-graph \( T_j := \bigcup_{j'=1}^{j-1} K_j^{(r)} \) and let \( \mathcal{Q}_j' \) contain all \( Q \in \mathcal{Q}_j \) such that \((Q \cup L_j) \leq \) does not contain any edge from \( T_j \) or \( L - L_j \).
  if \(|\mathcal{Q}_j'| \geq t\) then
    pick \( Q \in \mathcal{Q}_j' \) uniformly at random and let \( K_j := (Q \cup L_j) \leq \)
  else
    return ‘unsuccessful’
end if
end for

For every \((r - 1)\)-set \( S \subset V(G) \) and \( k \in [r - 1]_0 \), define \( \mathcal{J}_{S,k} := \{ j \in [m] : \max_{e \in L_j} |S \cap e| = k \} \).
Observe that if \( Y_j^S = 1 \), then \( K_j \) covers at most \( sf \) \( r \)-edges that contain \( S \). Therefore, we have

\[
|T_j(S)| \leq sf \sum_{j'=1}^{j-1} Y_j^S = sf \sum_{k=0}^{r-1} \sum_{j' \in \mathcal{J}_{S,k} \cap [j-1]} Y_j^S.
\]

The following claim thus implies the lemma.

Claim 1: With positive probability, we have \( \sum_{j' \in \mathcal{J}_{S,k} \cap [j-1]} Y_j^S \leq \gamma^{2/3} n \) for all \((r - 1)\)-sets \( S \), \( k \in [r - 1]_0 \) and \( j \in [m] \).

Fix an \((r - 1)\)-set \( S \), \( k \in [r - 1]_0 \) and \( j \in [m] \). For \( j' \in \mathcal{J}_{S,k} \), there are at most

\[
\sum_{e \in L_j} n^{f-|S \cup e|} \leq s n^{\max_{e \in L_j} (f-|S \cup e|)} = sn^{f-2r+1+k}
\]

\( f \)-sets that contain \( S \) and some edge of \( L_j \).

In order to apply Proposition 5.11, let \( j_1, \ldots, j_b \) be an enumeration of \( \mathcal{J}_{S,k} \cap [j-1] \). We then have for all \( a \in [b] \) and all \( y_1, \ldots, y_{a-1} \in \{0,1\} \) that

\[
P(Y_{j_a}^S = 1 \mid Y_{j_1}^S = y_1, \ldots, Y_{j_{a-1}}^S = y_{a-1}) \leq \frac{sn^{f-2r+1+k}}{t} = 2s\alpha^{-1}n^{-r+k+1}.
\]

Let \( p := \min\{2s\alpha^{-1}n^{-r+k+1}, 1\} \) and let \( B \sim \text{Bin}(|\mathcal{J}_{S,k} \cap [j-1]|, p) \).

Note that \( |\mathcal{J}_{S,k}| \leq (\binom{|S|}{k})\Delta(L) \leq (r^{-1})\gamma n^{r-k} \) by Fact 5.1. Thus,

\[
7EB = 7|\mathcal{J}_{S,k} \cap [j-1]| \cdot p \leq 7 \cdot \binom{r-1}{k} \gamma n^{r-k} \cdot 2s\alpha^{-1}n^{-r+k+1} \leq \gamma^{2/3} n.
\]

Therefore,

\[
P(\sum_{j' \in \mathcal{J}_{S,k} \cap [j-1]} Y_j^S \geq \gamma^{2/3} n) \leq P(B \geq \gamma^{2/3} n) \leq e^{-\gamma^{2/3} n}.
\]

A union bound now easily proves the claim.

Corollary 6.9. Let \( 1/n \ll \gamma \ll \alpha, 1/f \) and \( r \in [f-1] \). Suppose that \( F \) is an \( r \)-graph on \( f \) vertices.

Let \( G \) be a complex on \( n \) vertices and let \( H \subset G^{(r)} \) with \( \Delta(H) \leq \gamma n \) and \( |G^{(j)}(e)| \geq \alpha n^j \) for all \( e \in H \). Then there is a 1-well separated \( F \)-packing \( \mathcal{F} \) in \( G \) that covers all edges of \( H \) and such that \( \Delta(\mathcal{F}^{(r)}) \leq \sqrt{\gamma n} \).

Proof. Let \( e_1, \ldots, e_m \) be an enumeration of \( H \). For \( j \in [m] \), define \( L_j := \{ e_j \} \) and \( \mathcal{Q}_j := G^{(j)}(e) \).

Apply Lemma 6.7 to obtain \( K_1, \ldots, K_m \). For each \( j \in [m] \), let \( F_j \) be a copy of \( F \) with \( V(F_j) = K_j \) and such that \( e_j \in F_j \). Then \( \mathcal{F} := \{ F_1, \ldots, F_m \} \) is as desired.
We can conveniently combine Lemma 6.5 and Corollary 6.9 to deduce the following result. It allows us to make an \( r \)-graph divisible by deleting a small fraction of edges (even if we are forbidden to delete a certain set of edges \( H \)). We will prove a similar result (Corollary 9.5) in Section 11 under different assumptions.

**Corollary 6.10.** Let \( 1/n \ll \gamma, \varepsilon \ll \xi, 1/f \) and \( r \in [f - 1] \). Let \( F \) be an \( r \)-graph on \( f \) vertices. Suppose that \( G \) is a complex on \( n \) vertices which is \((\varepsilon, d, f, r)\)-regular for some \( d \geq \xi \) and \((\xi, f + r, r)\)-dense. Let \( H \subseteq G^{(r)} \) satisfy \( \Delta(H) \leq \varepsilon n \). Then there exists \( L \subseteq G^{(r)} - H \) such that \( \Delta(L) \leq \gamma n \) and \( G^{(r)} - L \) is \( F \)-divisible.

**Proof.** We clearly have \( |G^{(j)}(e)| \geq 0.5 \xi n^{j-r} \) for all \( e \in H \). Thus, by Corollary 6.9, there exists an \( F \)-packing \( F_0 \) in \( G \) which covers all edges of \( H \) and satisfies \( \Delta(\mathcal{F}_0^{(r)}) \leq \sqrt{\varepsilon} n \). By Proposition 5.9(i) and (ii), \( G' := G - \mathcal{F}_0^{(r)} \) is still \((2^{r+1} \varepsilon, d, f, r)\)-regular and \((\xi/2, f + r, r)\)-dense. Thus, by Lemma 6.5, there exists an \( F \)-packing \( \mathcal{F}_{nibble} \) in \( G' \) such that \( \Delta(L) \leq \gamma n \), where \( L := G^{(r)} - \mathcal{F}_{nibble}^{(r)} = G^{(r)} - \mathcal{F}_0^{(r)} - \mathcal{F}_{nibble}^{(r)} \subseteq G^{(r)} - H \). Clearly, \( G^{(r)} - L \) is \( F \)-divisible (in fact, \( F \)-decomposable). \( \square \)

### 7. Vortices

A vortex is best thought of as a sequence of nested ‘random-like’ subsets of the vertex set of a supercomplex \( G \). In our approach, the final set of the vortex has bounded size.

The main results of this section are Lemmas 7.4 and 7.5, where the first one shows that vortices exist, and the latter one shows that given a vortex, we can find an \( F \)-packing covering all edges which do not lie inside the final vortex set. We now give the formal definition of what it means to be a ‘random-like’ subset.

**Definition 7.1.** Let \( G \) be a complex on \( n \) vertices. We say that \( U \) is \((\varepsilon, \mu, \xi, f, r)\)-random in \( G \) if there exists an \( f \)-graph \( Y \) on \( V(G) \) such that the following hold:

1. (R1) \( U \subseteq V(G) \) with \( |U| = \mu n \pm n^{2/3} \);
2. (R2) there exists \( d \geq \xi \) such that for all \( x \in [f - r]_0 \) and all \( e \in G^{(r)} \), we have that
   \[ |\{Q \in G[Y]^{(f)}(e) : Q \cap U = x\}| = (1 \pm \varepsilon) \text{bin}(f - r, \mu, x)dn^{f-r}; \]
3. (R3) for all \( e \in G^{(r)} \) we have \( |G[Y]^{(f+r)}(e)| \geq \xi(\mu n)^f \);
4. (R4) for all \( h \in [r]_0 \) and all \( B \subseteq G^{(h)} \) with \( 1 \leq |B| \leq 2^h \) we have that \( \bigcap_{b \in B} G(b) \) is an \((\varepsilon, \xi, f - h, r - h)\)-complex.

We record the following easy consequences for later use.

**Fact 7.2.** The following hold.

1. (i) If \( G \) is an \((\varepsilon, \xi, f, r)\)-supercomplex, then \( V(G) \) is \((\varepsilon/\xi, 1, \xi, f, r)\)-random in \( G \).
2. (ii) If \( U \) is \((\varepsilon, \mu, \xi, f, r)\)-random in \( G \), then \( G[U] \) is an \((\varepsilon, \xi, f, r)\)-supercomplex.

Here, (ii) follows immediately from (R4). Note that (R4) is stronger in the sense that \( B \) is not restricted to \( U \). Having defined what it means to be a ‘random-like’ subset, we can now define what a vortex is.

**Definition 7.3 (Vortex).** Let \( G \) be a complex. An \((\varepsilon, \mu, \xi, f, r, m)\)-vortex in \( G \) is a sequence \( U_0 \supseteq U_1 \supseteq \cdots \supseteq U_\ell \) such that

1. (V1) \( U_0 = V(G) \);
2. (V2) \( |U_i| = |\mu U_{i-1}| \) for all \( i \in [\ell] \);
3. (V3) \( |U_\ell| = m \);
4. (V4) for all \( i \in [\ell] \), \( U_i \) is \((\varepsilon, \mu, \xi, f, r)\)-random in \( G[U_{i-1}] \);
5. (V5) for all \( i \in [\ell - 1] \), \( U_i \setminus U_{i+1} \) is \((\varepsilon, \mu(1 - \mu), \xi, f, r)\)-random in \( G[U_{i-1}] \).

We will show in Section 7.2 that a vortex can be found in a supercomplex by repeatedly taking random subsets.
Lemma 7.4. Let $1/m' \ll \varepsilon \ll \mu, \xi, 1/f$ such that $\mu \leq 1/2$ and $r \in [f - 1]$. Let $G$ be an $(\varepsilon, \xi, f, r)$-supercomplex on $n \geq m'$ vertices. Then there exists a $(2\sqrt{\varepsilon}, \mu, \xi - \varepsilon, f, r, m)$-vortex in $G$ for some $\mu m' \leq m \leq m'$.

The following is the main lemma of this section. Given a vortex in a supercomplex $G$, it allows us to cover all edges of $G^{(r)}$ except possibly some from inside the final vortex set. We will prove Lemma 7.5 in Section 7.4.

Lemma 7.5. Let $1/m \ll 1/\kappa \ll \varepsilon \ll \mu \ll \xi, 1/f$ and $r \in [f - 1]$. Assume that $(\ast)_k$ is true for all $k \in [r - 1]$. Let $F$ be a weakly regular $r$-graph on $f$ vertices. Let $G$ be an $F$-divisible $(\varepsilon, \xi, f, r)$-supercomplex and $U_0 \supseteq U_1 \supseteq \cdots \supseteq U_t$ an $(\varepsilon, \mu, \xi, f, r, m)$-vortex in $G$. Then there exists a $4\kappa$-well separated $F$-packing $F$ in $G$ which covers all edges of $G^{(r)}$ except possibly some inside $U_t$.

The proof of Lemma 7.5 consists of an ‘iterative absorption’ procedure, where the key ingredient is the Cover down lemma (Lemma 7.7). Roughly speaking, given a supercomplex $G$ and a ‘random-like’ subset $U \subseteq V(G)$, the Cover down lemma allows us to find a ‘partial absorber’ $H \subseteq G^{(r)}$ such that for any sparse $L \subseteq G^{(r)}$, $H \cup L$ has an $F$-packing which covers all edges of $H \cup L$ except possibly some inside $U$. Together with the $F$-nibble lemma (Lemma 6.5), this allows us to cover all edges of $G$ except possibly some inside $U$ whilst using only few edges inside $U$. Indeed, set aside $H$ as above, which is reasonably sparse. Then apply the Lemma 6.5 to $G - G^{(r)}[U] - H$ to obtain an $F$-packing $F_{\text{nibble}}$ with a very sparse leftover $L$. Combine $H$ and $L$ to find an $F$-packing $F_{\text{dean}}$ whose leftover lies inside $U$.

Now, if $U_0 \supseteq U_1 \supseteq \cdots \supseteq U_t$ is a vortex, then $U_1$ is ‘random-like’ in $G$ and thus we can cover all edges which are not inside $U_1$ by using only few edges inside $U_1$ (and in this step we forbid edges inside $U_2$ from being used.) Then $U_3$ is still ‘random-like’ in the remainder of $G[U_1]$, and hence we can iterate until we have covered all edges of $G$ except possibly some inside $U_t$.

7.1. The Cover down lemma. We now provide the formal statement of the Cover down lemma. We will prove it in Section 10.

Definition 7.6. Let $G$ be a complex on $n$ vertices and $H \subseteq G^{(r)}$. We say that $G$ is $(\xi, f, r)$-dense with respect to $H$ if for all $e \in G^{(r)}$, we have $|G[H \cup \{e\}]^\ast(e)| \geq \xi n^{f-r}$.

Lemma 7.7 (Cover down lemma). Let $1/n \ll 1/\kappa \ll \gamma \ll \varepsilon \ll \nu \ll \mu, \xi, 1/f$ and $r \in [f - 1]$ with $\mu \leq 1/2$. Assume that $(\ast)_i$ is true for all $i \in [r - 1]$ and that $F$ is a weakly regular $r$-graph on $f$ vertices. Let $G$ be a complex on $n$ vertices and suppose that $U$ is $(\varepsilon, \mu, \xi, f, r)$-random in $G$. Let $\tilde{G}$ be a complex on $V(G)$ with $G \subseteq \tilde{G}$ such that $\tilde{G}$ is $(\varepsilon, f, r)$-dense with respect to $G^{(r)} - G^{(r)}[\tilde{U}]$, where $\tilde{U} := V(G) \setminus U$.

Then there exists a subgraph $H^* \subseteq \tilde{G}^{(r)} - G^{(r)}[\tilde{U}]$ with $\Delta(H^*) \leq \nu n$ such that for any $L \subseteq \tilde{G}^{(r)}$ with $\Delta(L) \leq \gamma n$ and $H^* \cup L$ being $F$-divisible and any $(r + 1)$-graph $O$ on $V(G)$ with $\Delta(O) \leq \gamma n$, there exists a $\kappa$-well separated $F$-packing in $\tilde{G}[H^* \cup L] - O$ which covers all edges of $H^* \cup L$ except possibly some inside $U$.

Roughly speaking, the proof of the Cover down lemma proceeds as follows. Suppose that we have already chosen $H^*$ and that $L$ is any sparse (leftover) $r$-graph. For an edge $e \in H^* \cup L$, we refer to $|e \cap U|$ as its type. Since $L$ is very sparse, we can greedily cover all edges of $L$ using edges of $H^*$ in a first step. In particular, this covers all type-0-edges. We will now continue and cover all type-1-edges. Note that every type-1-edge contains a unique $S \in \binom{V(G)}{r-1}\setminus U$. For a given set $S \in \binom{V(G)}{r-1}\setminus U$, we would like to cover all remaining edges of $H^*$ that contain $S$ simultaneously. Assuming a suitable choice of $H^*$, this can be achieved as follows. Let $L_S$ be the link graph of $S$ after the first step. Let $T \in \binom{V(F)}{r-1}$ be such that $F(T)$ is non-empty. By Proposition 5.3, $L_S$ will be $F(T)$-divisible. Thus, by $(\ast)_1$, $L_S$ has a $\kappa$-well separated $F(T)$-decomposition $F'_S$. Proposition 7.9 below implies that we can ‘extend’ $F'_S$ to a $\kappa$-well separated $F$-packing $F_S$ which covers all edges that contain $S$.

However, in order to cover all type-1-edges, we need to obtain such a packing $F_S$ for every $S \in \binom{V(G)}{r-1}\setminus U$, and these packings are to be disjoint for their union to be a $\kappa$-well separated
\[ F\)-packing again. The real difficulty thus lies in choosing \( H^* \) in such a way that the link graphs \( L_S \) do not interfere too much with each other, and then to choose the decompositions \( F'_S \) sequentially (see the discussion in the beginning of Section 10). We would then continue to cover all type-2-edges using \((*)_2\), etc., until we finally cover all type-(\( r-1 \))-edges using \((*)_{r-1}\). The only remaining edges are then type-\( r \)-edges, which are contained in \( U \), as desired.

We now show how the notion of well separated \( F\)-packings allows us to ‘extend’ a decomposition of a link complex to a packing which covers all edges that contain a given set \( S \) (cf. the discussion in Section 4.2).

**Definition 7.8.** Let \( F \) be an \( r \)-graph, \( i \in [r - 1] \) and assume that \( T \in (V(F)^i) \) is such that \( F(T) \) is non-empty. Let \( G \) be a complex and \( S \in (V(G)^i) \). Suppose that \( F' \) is a well separated \( F(T) \)-packing in \( G(S) \). We then define \( S \triangle F' \) as follows: For each \( F' \in F' \), let \( F'_d \) be an (arbitrary) copy of \( F \) on vertex set \( S \cup V(F') \) such that \( F'_{d}(S) = F' \). Let

\[ S \triangle F' := \{ F'_{d}: F' \in F' \} \]

The following proposition is crucial and guarantees that the above extension yields a packing which covers the desired set of edges. It is also used in the construction of so-called ‘transformers’ (see Section 8.1).

**Proposition 7.9.** Let \( F, r, i, T, G, S \) be as in Definition 7.8. Let \( L \subseteq G(S)^{(r-i)} \). Suppose that \( F' \) is a \( \kappa \)-well separated \( F(T) \)-decomposition of \( G(S)[L] \). Then \( F := S \triangle F' \) is a \( \kappa \)-well separated \( F\)-packing in \( G \) and \( \{ e \in F(r): S \subseteq e \} = S \cup L \).

In particular, if \( L = G(S)^{(r-i)} \), i.e. if \( F' \) is a \( \kappa \)-well separated \( F(T) \)-decomposition of \( G(S) \), then \( F \) is a \( \kappa \)-well separated \( F\)-packing in \( G \) which covers all \( r \)-edges of \( G \) that contain \( S \).

**Proof.** We first check that \( F \) is an \( F\)-packing in \( G \). Let \( f := |V(F)| \). For each \( F' \in F' \), we have \( V(F') \subseteq G(S)[L]^{(r-i)} \subseteq G(S)^{(r-i)} \). Hence, \( V(F'_d) \subseteq G(F) \). In particular, \( G(F)[V(F'_d)] \) is a clique and thus \( F'_d \) is a subgraph of \( G(F) \). Suppose, for a contradiction, that for distinct \( F', F'' \in F' \), \( F'_d \) and \( F''_d \) both contain \( e \in G(F) \). By (WS1) we have that \( V(F') \cap V(F'') \) is a \( \kappa \)-well separated \( F\)-packing in \( G(S)[L] \), we have \( e \notin S \subseteq G(S)[L] \), and thus \( e \setminus S \) belongs to at most one of \( F' \) and \( F'' \). Without loss of generality, assume that \( e \setminus S \notin F' \). Then we have \( e \setminus S \notin F'_d(S) \) and thus \( e \notin F'_d \); a contradiction. Thus, \( F \) is an \( F\)-packing in \( G \).

We next show that \( F \) is \( \kappa \)-well separated. Clearly, for distinct \( F', F'' \in F' \), we have \( V(F'_d) \cap V(F''_d) \) is a \( \kappa \)-well separated \( F\)-packing in \( G(S)[L] \), we have \( e \setminus S \subseteq G(S)[L] \), we have \( e \notin S \subseteq G(S)[L] \), and thus \( e \setminus S \) belongs to at most one of \( F' \) and \( F'' \). Without loss of generality, assume that \( e \setminus S \notin F' \). Then we have \( e \setminus S \notin F'_d(S) \) and thus \( e \notin F'_d \); a contradiction. Thus, \( F \) is an \( F\)-packing in \( G \).

Finally, we check that \( \{ e \in F(r): S \subseteq e \} = S \cup L \). Let \( e \) be any \( r \)-set with \( S \subseteq e \). By Definition 7.8, we have \( e \in F(r) \) if and only if \( e \setminus S \subseteq F^{(r-i)} \). Since \( F \) is an \( F(T) \)-decomposition of \( G(S)[L] \), we have \( e \setminus S \subseteq F^{(r-i)} \) if and only if \( e \setminus S \subseteq L \). Thus, \( e \in F(r) \) if and only if \( e \in S \cup L \).

7.2. Existence of vortices. The goal of this subsection is to prove Lemma 7.4, which guarantees the existence of a vortex in a supercomplex.

**Fact 7.10.** For all \( p_1, p_2 \in [0, 1] \) and \( i, n \in \mathbb{N}_0 \), we have

\[ \sum_{j=i}^{n} \text{bin}(n, p_1, j)\text{bin}(j, p_2, i) = \text{bin}(n, p_1 p_2, i). \]

**Proposition 7.11.** Let \( 1/n \ll \varepsilon \ll \mu_1, \mu_2, 1 - \mu_2, \xi, 1/f \) and \( r \in [f - 1] \). Let \( G \) be a complex on \( n \) vertices and suppose that \( U = (\varepsilon, \mu_1 + \xi, f, r) \)-random in \( G \). Let \( U' \) be a random subset of \( U \) obtained by including every vertex from \( U \) independently with probability \( \mu_2 \). Then whp for all \( W \subseteq U \) of size \( |W| \leq |U|^{3/5} \), \( U' \setminus W \) is \( (\varepsilon + 0.5|U|^{-1/6}, \mu_1 \mu_2, \xi - 0.5|U|^{-1/6}, f, r) \)-random in \( G \).
Thus, using Corollary 5.14 and a union bound, we deduce that whp for all $e \in W'$, we have |

We now check (R3). Suppose $x \in [f-r]_0$ and let $\mathcal{Q}_x := \{Q \in \mathcal{G}[Y]^{[f+r]}(e) : |Q \cap U' = x\}$. Consider $e \in G^{(r)}$ and $x, y \in [f-r]_0$. We view $\mathcal{Q}_{x,y}$ as a $(f-r)$-graph and consider the random subgraph $\mathcal{Q}_{x,y}$ containing all $Q \in \mathcal{Q}_{x,y}$ such that $|Q \cap U'| = y$.

By the random choice of $U'$, for all $e \in G^{(r)}$ and $x, y \in [f-r]_0$, we have $E[\mathcal{Q}_{x,y}] = bin(x, \mu_2, y) |\mathcal{Q}_{x,y}|$.

Thus, by Corollary 5.14 we have $|\mathcal{Q}_{e,x,y}| = (1 \pm \varepsilon)bin(f-r, \mu_1, x)dn^{f-r}$, where $\mathcal{Q}_{e,x}$ := $\{Q \in \mathcal{G}[Y]^{[f]}(e) : |Q \cap U' = x\}$. Consider $e \in G^{(r)}$ and $x, y \in [f-r]_0$. We view $\mathcal{Q}_{e,x}$ as a $(f-r)$-graph and consider the random subgraph $\mathcal{Q}_{e,x,y}$ containing all $Q \in \mathcal{Q}_{e,x}$ such that $|Q \cap U'| = y$.

By the random choice of $U'$, for all $e \in G^{(r)}$ and $x, y \in [f-r]_0$, we have $E[\mathcal{Q}_{e,x,y}] = bin(x, \mu_2, y) |\mathcal{Q}_{e,x,y}|$.

Thus, by Corollary 5.14 we have $|\mathcal{Q}_{e,x,y}| = (1 \pm \varepsilon)bin(x, \mu_2, y) |\mathcal{Q}_{e,x}|$

$(1 \pm \varepsilon)bin(x, \mu_2, y) |\mathcal{Q}_{e,x}|$

We now check (R3). Suppose $x \in G^{(r)}$ and let $\mathcal{Q}_x := \{Q \in \mathcal{G}[Y]^{[f+r]}(e) : |Q \cap U' = x\}$. We have $|\mathcal{Q}_x| \geq \xi(\mu_1n)^f$. Consider the random subgraph of $\mathcal{Q}_x$ consisting of all $f$-sets $Q \in \mathcal{Q}_x$ satisfying $Q \subseteq U'$. For every $Q \in \mathcal{Q}_x$, we have $P(Q \subseteq U') = \mu_2^f$. Hence, $E[\mathcal{Q}_x] = \mu_2^f |\mathcal{Q}_x| \geq \xi(\mu_1n)^f$. Thus, using Corollary 5.14 and a union bound, we deduce that $whp$ for all $e \in G^{(r)}$, we have $|\mathcal{G}[Y]^{[f+r]}(e)[U']| \geq (1-|U'|^{-1/5})\xi(\mu_1n)^f$. Assuming that this holds for $U'$, it is easy to see that for all $W \subseteq U$ of size $|W| \leq |U|^{3/5}$, we have $|\mathcal{G}[Y]^{[f+r]}(e)[U' \triangle W]| \geq (1-|U'|^{-1/5})\xi(\mu_1n)^f - |W|n^{-f-1} \geq (1-2|U'|^{-1/5})(\mu_1n)^f$.

Finally, we check (R4). Let $h \in [r]_0$ and $B \subseteq G^{(h)}$ with $1 \leq |B| \leq 2^h$. Since $U$ is $(e, \mu_1, \xi, f, r)$-random in $G$, we have $\bigcap_{b \in B} G(b)[U]$ is an $(e, \xi, f, h-r, h)$-complex. Then, by Proposition 5.16, with probability at least $1 - e^{-|U'|/8}$, $\bigcap_{b \in B} G(b)[U' \triangle W]$ is an $(e + 4|U|^{-1/5}, \xi - 3|U|^{-1/5}, f, h-r, h)$-complex for all $W \subseteq U$ of size $|W| \leq |U|^{3/5}$. Thus, a union bound yields the desired result.

**Proposition 7.12.** Let $1/n \ll \varepsilon \ll \mu_1, \mu_2, 1 - \mu_2, \xi, 1/f$ and $r \in [f-1]$. Let $G$ be a complex on $n$ vertices and let $U \subseteq V(G)$ be of size $[\mu_1n]$ and $(e, \mu_1, \xi, f, r)$-random in $G$. Then there exists $U' \subseteq U$ of size $[\mu_2|U|]$ such that

(i) $U$ is $(\varepsilon + |U|^{-1/6}, \mu_2, \xi - |U|^{-1/6}, f, r)$-random in $G[U]$ and

(ii) $U \setminus U$ is $(\varepsilon + |U|^{-1/6}, \mu_1(1 - \mu_2), \xi - |U|^{-1/6}, f, r)$-random in $G$.

**Proof.** Pick $U' \subseteq U$ randomly by including every vertex from $U$ independently with probability $\mu_2$. Clearly, by Lemma 5.10(i), we have with probability at least $1 - 2e^{-2|U'|^{1/7}}$ that $|U'| = \mu_2|U| \pm |U'|^{1/7}$.

It is easy to see that $U$ is $(\varepsilon + 0.5|U|^{-1/6}, 1 - \xi - 0.5|U|^{-1/6}, f, r)$-random in $G[U]$. Hence, by Proposition 7.11, whp $U \setminus U$ is $(\varepsilon + |U|^{-1/6}, \mu_1(1 - \mu_2), \xi - |U|^{-1/6}, f, r)$-random in $G[\bar{U}]$ for all $W \subseteq U$ of size $|W| \leq |U|^{3/5}$. Moreover, since $U'' := U \setminus U'$ is a random subgraph obtained by including every vertex from $U$ independently with probability $1 - \mu_2$, Proposition 7.11 implies that whp $U'' \setminus U'$ is $(\varepsilon + 0.5|U|^{-1/6}, \mu_1(1 - \mu_2), \xi - 0.5|U|^{-1/6}, f, r)$-random in $G$ for all $W \subseteq U$ of size $|W| \leq |U|^{3/5}$. 

Let $U'$ be a set that has the above properties. Let $W \subseteq V(G)$ be a set with $|W| \leq |U|^{3/5}$ such that $|U' \triangle W| = |\mu_2[U]|$ and let $\bar{U} := U' \triangle W$. By the above, $\bar{U}$ satisfies (i) and (ii).

We can now obtain a vortex by inductively applying Proposition 7.12.

**Proof of Lemma 7.4.** Recursively define $n_0 := n$ and $n_i := \lfloor \mu n_{i-1} \rfloor$. Observe that $\mu^i n \geq n_i \geq \mu^i n - 1/(1 - \mu)$. Further, for $i \in \mathbb{N}$, let $a_i := 2n^{-1/6} \sum_{j \in [i]} \mu^{-j/6}$. Let $\ell := 1 + \max\{i \geq 0 : n_i \geq m\}$ and let $m := n_\ell$. Note that $|\mu m| \leq m \leq m'$. Moreover, we have that

$$a_\ell = 2n^{-1/6} \mu^{\ell/6} - 1 \leq 2(\mu^{\ell/6} - 1) \leq \frac{2(\mu^{\ell/6} - 1)}{1 - \mu^{1/6}} \leq \frac{2m^{-1/6}}{1 - \mu^{1/6}} \leq \varepsilon$$

since $\mu^{\ell-1} n \geq n_{\ell-1} \geq m'$.

By Fact 7.2, $U_0 := V(G)$ is $(\varepsilon/\xi, 1, \xi, f, r)$-random in $G$. Hence, by Proposition 7.12, there exists a set $U_1 \subseteq U_0$ of size $n_1$ such that $U_1$ is $(\sqrt{\varepsilon} + a_1, \mu, \xi - a_1, f, r)$-random in $G[U_0]$. If $\ell = 1$, this completes the proof, so assume that $\ell \geq 2$.

Now, suppose that for some $i \in [\ell - 1]$, we have already found a $(\sqrt{\varepsilon} + a_i, \mu, \xi - a_i, f, r)$-vortex $U_{0,i}, \ldots, U_i$ in $G$. Note that this is true for $i = 1$. In particular, $U_i$ is $(\sqrt{\varepsilon} + a_i, \mu, \xi - a_i, f, r)$-random in $G[U_{i-1}]$ by (V4). By Proposition 7.12, there exists a subset $U_{i+1}$ of size $n_{i+1}$ such that $U_{i+1}$ is $(\sqrt{\varepsilon} + a_i, n_i^{-1/6}, \mu, \xi - a_i - n_i^{-1/6}, f, r)$-random in $G[U_i]$ and $U_i \setminus U_{i+1}$ is $(\sqrt{\varepsilon} + a_i + n_i^{-1/6}, \mu(1 - \xi), \xi - a_i - n_i^{-1/6}, f, r)$-random in $G[U_{i-1}]$. Thus, $U_0, \ldots, U_{i+1}$ is a $(\sqrt{\varepsilon} + a_{i+1}, \mu, \xi - a_{i+1}, f, r, n_{i+1})$-vortex in $G$.

Finally, $U_0, \ldots, U_{\ell}$ is an $(\sqrt{\varepsilon} + a_{\ell}, \mu, \xi - a_{\ell}, f, r, m)$-vortex in $G$.

**Proposition 7.13.** Let $1/n \ll \varepsilon \ll \mu, \xi, 1/f$ such that $\mu \leq 1/2$ and $r \in [f - 1]$. Suppose that $G$ is a complex on $n$ vertices and $U$ is $(\varepsilon, \mu, \xi, f, r)$-random in $G$. Suppose that $L \subseteq G^{(r)}$ and $O \subseteq G^{(r+1)}$ satisfy $\Delta(L) \leq \varepsilon n$ and $\Delta(O) \leq \varepsilon n$. Then $U$ is still $(\sqrt{\varepsilon}, \mu, \xi - \sqrt{\varepsilon}, f, r)$-random in $G - L - O$.

**Proof.** Clearly, (R1) still holds. Moreover, using Proposition 5.7 it is easy to see that (R2) and (R3) are preserved. To see (R4), let $h \in [r]_0$ and $B \subseteq (G - L - O)^{(h)}$ with $1 \leq |B| \leq 2^h$. By assumption, we have that $\bigcap_{b \in B} G(b)[U]$ is an $(\varepsilon, \xi, f - h, r - h)$-complex. By Fact 5.8, we can obtain $\bigcap_{b \in B} G(b)[U]$ from $\bigcap_{b \in B} G(b)[U]$ by successively deleting $(r - |S|)$-graphs $L(S)$ and $(r + 1 - |S|)$-graphs $O(S)$, where $S \subseteq b \in B$. There are at most $2|B|2^h \leq 2^{2h+1}$ such graphs. By Fact 5.1, we have $\Delta(L(S)) \leq \varepsilon n \leq \varepsilon^{2/3}|U - \bigcup B|$ if $|S| \leq r$. If $|S| = r$, we have $S \in B$ and thus $L(S)$ is empty, in which case we can ignore its removal. Moreover, again by Fact 5.1, we have $\Delta(O(S)) \leq \varepsilon n \leq \varepsilon^{2/3}|U - \bigcup B|$ for all $S \subseteq b \in B$. Thus, a repeated application of Proposition 5.9(iv) (with $r - |S|, r - h, f - h, L(S), \varepsilon^{2/3}$ playing the roles of $r', r, f, H, \gamma$ or with $r + 1 - |S|, r - h, f - h, O(S), \varepsilon^{2/3}$ playing the roles of $r', r, f, H, \gamma$, respectively) shows that $\bigcap_{b \in B} (G - L - O)(b)[U]$ is a $(\sqrt{\varepsilon}, \xi - \sqrt{\varepsilon}, f - h, r - h)$-complex, as needed.

### 7.3. Existence of cleaners

Recall that the Cover down down lemma guarantees the existence of a suitable ‘cleaning graph’ or ‘partial absorber’ which allows us to ‘clean’ the leftover of an application of the $F$-nibble lemma in the sense that the new leftover is guaranteed to lie in the next vortex set. For technical reasons, we will in fact find all cleaning graphs first (one for each vortex set) and set them aside even before the first nibble.

The aim of this subsection is to apply the Cover down lemma to each ‘level’ $i$ of the vortex to obtain a ‘cleaning graph’ $H_i$ (playing the role of $H^*$) for each $i \in [\ell]$ (see Lemma 7.15). Let $G$ be a complex and $U_0 \supseteq U_1 \supseteq \cdots \supseteq U_\ell$ be a vortex in $G$. We say that $H_1, \ldots, H_\ell$ is a $(\gamma, \nu, \kappa, F)$-cleaner (for the said vortex) if the following hold for all $i \in [\ell]$:

1. $H_i \subseteq G^{(r)}[U_{i-1}] - G^{(r)}[U_{i+1}]$, where $U_{\ell+1} := \emptyset$;
2. $\Delta(H_i) \leq \nu[U_{i-1}]$;
3. $H_i$ and $H_{i+1}$ are edge-disjoint, where $H_{\ell+1} := \emptyset$;
(C4) whenever \( L \subseteq G^{(r)}[U_{i-1}] \) is such that \( \Delta(L) \leq \gamma|U_{i-1}| \) and \( H_i \cup L \) is \( F \)-divisible and \( O \) is an \((r + 1)\)-graph on \( U_{i-1} \) with \( \Delta(O) \leq \gamma|U_{i-1}| \), there exists a \( \kappa \)-well separated \( F \)-packing \( \mathcal{F} \) in \( G[H_i \cup L][U_{i-1}] - O \) which covers all edges of \( H_i \cup L \) except possibly some inside \( U_i \).

Note that (C1) and (C3) together imply that \( H_1, \ldots, H_t \) are edge-disjoint. The following proposition will be used to ensure (C3).

**Proposition 7.14.** Let \( 1/n \ll \varepsilon \ll \mu, \xi, 1/f \) and \( r \in [f - 1] \). Let \( \xi' := \xi(1/2)^{(8f + 1)} \). Let \( G \) be a complex on \( n \) vertices and let \( U \subseteq V(G) \) of size \( \mu n \) and \((\varepsilon, \mu, \xi, f, r)\)-random in \( G \). Suppose that \( H \) is a random subgraph of \( G^{(r)} \) obtained by including every edge of \( G^{(r)} \) independently with probability \( 1/2 \). Then with probability at least \( 1 - e^{-n^{1/10}} \),

\[ (i) \quad U \text{ is } (\sqrt{\varepsilon}, \mu, \xi', f, r)\text{-random in } G[H] \text{ and} \]
\[ (ii) \quad G \text{ is } (\sqrt{\varepsilon}, f, r)\text{-dense with respect to } H - G^{(r)}[U], \text{ where } U := V(G) \setminus U. \]

**Proof.** Let \( Y \subseteq G^{(f)} \) and \( d \geq \xi \) be such that (R1)–(R4) hold for \( U \) and \( G \). We first consider (i). Clearly, (R1) holds. We next check (R2). For \( e \in G^{(r)} \) and \( x \in [f - r]_0 \), let \( Q_{e, x} := \{ Q \in G[Y]^{(f)}(e) : |Q \cap U| = x \} \). Thus, \( |Q_{e, x}| = (1 \pm \varepsilon)\binom{f - r, \mu, x}{dn}^{f - r} \).

Next, we check (R3). By assumption, we have \( |G[Y]^{(f + r)}(e)[U]| \geq \xi(\mu n)^f \) for all \( e \in G^{(r)} \). Let \( Q_e := G[Y]^{(f + r)}(e)[U] \) and consider the random subgraph \( Q_e' \) containing all \( Q \in Q_{e, x} \) such that \((Q_{r,e}) \setminus \{e\} \subseteq H \). For each \( Q \in Q_{e, x} \), we have \( \mathbb{P}(Q \in Q_{e, x}') = (1/2)^{(f + r) - 1} \). Thus, using Corollary 5.14 we deduce that with probability at least \( 1 - e^{-n^{1/6}} \) we have

\[
|Q_{e, x}'| = (1 \pm \varepsilon)|E|Q_{e, x}'| = (1 \pm \varepsilon)(1/2)^{(f + r) - 1}|E|Q_{e, x}'| = (1 \pm \varepsilon)d'\binom{f - r, \mu, x}{dn}^{f - r},
\]

where \( d' := d(1/2)^{(f + r) - 1} \geq \xi' \). Thus, a union bound yields that with probability at least \( 1 - e^{-n^{1/7}}, \) (R2) holds.

Next, we check (R4). Let \( h \in [r]_0 \) and \( B \subseteq G^{(h)} \) with \( 1 \leq |B| \leq 2^h \). We know that \( \bigcap_{b \in B} G^{(h)}[U] \) is an \((\varepsilon, \xi, f, h, r - h)\)-complex. By Proposition 5.18 (applied with \( G[U] \cup \bigcup B \), \( \{G[U] \cup \bigcup B^{(r)}\} \)

playing the roles of \( G, \mathcal{P} \), with probability at least \( 1 - e^{-|U|^{1/8}} \), \( \bigcap_{b \in B} G[H^{(h)}[b][U]] \) is a \((\varepsilon, \xi', f - h, r - h)\)-complex. Thus, a union bound over all \( h \in [r]_0 \) and \( B \subseteq G^{(h)} \) with \( 1 \leq |B| \leq 2^h \) yields that with probability at least \( 1 - e^{-n^{1/8}}, \) (R4) holds.

Finally, we check (ii). Consider \( e \in G^{(r)} \) and let \( Q_e := G[(G^{(r)}[U \setminus e])^{(f)}(e)] \). Note by (R2), we have \( |G[Y]^{(f)}(e)[U]| = (1 \pm \varepsilon)\binom{f - r, \mu, f - r}{dn}^{f - r} \), so \( |Q_e| \geq |G[Y]^{(f)}(e)[U]| \geq (1 - \varepsilon)\mu \mu^{f - r}n^{f - r} \). We view \( Q_e \) as a \((f - r)\)-graph and consider the random subgraph \( Q_e' \) containing all \( Q \in Q_{e, x} \) such that \((Q_{r,e}) \setminus \{e\} \subseteq H \). For each \( Q \in Q_{e, x} \), we have \( \mathbb{P}(Q \in Q_{e, x}') = (1/2)^{(f + r) - 1} \). Thus, using Corollary 5.14 we deduce that with probability at least \( 1 - e^{-n^{1/6}} \) we have

\[
|Q_{e, x}'| \geq 0.9|E|Q_{e, x}'| \geq 0.9(1/2)^{(f + r) - 1}(1 - \varepsilon)\mu \mu^{f - r}n^{f - r} \geq \sqrt{\varepsilon}n^{f - r}.
\]

A union bound easily implies that with probability at least \( 1 - e^{-n^{1/7}} \), this holds for all \( e \in G^{(r)} \). \( \Box \)

The following lemma shows that cleaners exist.

**Lemma 7.15.** Let \( 1/m \ll 1/k \ll \gamma \ll \varepsilon \ll \nu \ll \mu, \xi, 1/f \) be such that \( \mu \leq 1/2 \) and \( r \in [f - 1] \). Assume that \((\ast)_i \) is true for all \( i \in [r - 1] \) and that \( F \) is a weakly regular \( r \)-graph on \( f \) vertices.
Let \( G \) be a complex and \( U_0 \supseteq U_1 \supseteq \cdots \supseteq U_\ell \) an \((\varepsilon, \mu, \xi, f, r, m)\)-vortex in \( G \). Then there exists a \((\gamma, \nu, \kappa, F)\)-cleaner.

**Proof.** For \( i \in [\ell] \), define \( U'_i := U_i \setminus U_{i+1} \), where \( U_{i+1} := \emptyset \). For \( i \in [\ell - 1] \), let \( \mu_i := \mu(1 - \mu) \), and let \( \mu_\ell := \mu \). By (V4) and (V5), we have for all \( i \in [\ell] \) that \( U'_i \) is \((\varepsilon, \mu_i, \xi, f, r)\)-random in \( G[U_{i-1}] \).

Split \( G^{(r)} \) randomly into \( G_0 \) and \( G_1 \), that is, independently for every edge \( e \in G^{(r)} \), put \( e \) into \( G_0 \) with probability \( 1/2 \) and into \( G_1 \) otherwise. We claim that with positive probability, the following hold for every \( i \in [\ell] \):

(i) \( U'_i \) is \((\sqrt{\varepsilon}, \mu_i, \xi(1/2)^{(\ell+1)} , f, r)\)-random in \( G[G_{1 \mod 2}][U_{i-1}] \);

(ii) \( G[U_{i-1}] \) is \((\sqrt{\varepsilon}, f, r)\)-dense with respect to \( G_{i \mod 2}[U_{i-1}] - G^{(r)}[U_{i-1} \setminus U'_i] \).

By Proposition 7.14, the probability that (i) or (ii) do not hold for \( i \in [\ell] \) is at most \( e^{-[U_{i-1}]^{1/10}} \leq |U_{i-1}|^{-2} \). Since \( \sum_{i=1}^\ell |U_{i-1}|^{-2} < 1 \), we deduce that with positive probability, (i) and (ii) hold for all \( i \in [\ell] \).

Therefore, there exist \( G_0, G_1 \) satisfying the above properties. For every \( i \in [\ell] \), we will find \( H_i \) using the Cover down lemma (Lemma 7.7). Let \( i \in [\ell] \). Apply Lemma 7.7 with the following objects/parameters:

| object/parameter | \( G[G_{1 \mod 2}][U_{i-1}] \) | \( U'_i \) | \( G[U_{i-1}] \) | \( F \) | \( |U_{i-1}| \) | \( \kappa \) | \( \gamma \) | \( \sqrt{\varepsilon} \) | \( \nu \) | \( \mu_i \) | \( \xi(1/2)^{(\ell+1)} \) | \( f \) | \( r \) |
|------------------|-----------------|--------|-----------------|--------|-----------------|--------|--------|--------|--------|--------|-----------------|--------|--------|
| playing the role of | \( G \) | \( U \) | \( G \) | \( F \) | \( n \) | \( \kappa \) | \( \gamma \) | \( \varepsilon \) | \( \nu \) | \( \mu \) | \( \xi \) | \( f \) | \( r \) |

Hence, there exists

\[ H_i \subseteq G_{i \mod 2}[U_{i-1}] - G_{i \mod 2}[U_{i-1} \setminus U'_i] \subseteq G_{i \mod 2}[U_{i-1}] - G^{(r)}[U_{i+1}] \]

with \( \Delta(H_i) \leq \nu|U_{i-1}| \) and the following ‘cleaning’ property: for all \( L \subseteq G^{(r)}[U_{i-1}] \) with \( \Delta(L) \leq \gamma|U_{i-1}| \) such that \( H_i \cup L \) is \( F \)-divisible and all \((r + 1)\)-graphs \( O \) on \( U_{i-1} \) with \( \Delta(O) \leq \gamma|U_{i-1}| \), there exists a \( \kappa \)-well separated \( F \)-packing \( F \) in \( G[H_i \cup L][U_{i-1}] - O \) which covers all edges of \( H_i \cup L \) except possibly some inside \( U'_i \subseteq U_i \). Thus, (C1), (C2) and (C4) hold.

Since \( G_0 \) and \( G_1 \) are edge-disjoint, (C3) holds as well. Thus, \( H_1, \ldots, H_\ell \) is a \((\gamma, \nu, \kappa, F)\)-cleaner. \( \square \)

### 7.4. Obtaining a near-optimal packing

Recall that Lemma 7.5 guarantees an \( F \)-packing covering all edges except those in the final set \( U_\ell \) of a vortex. We prove this by applying successively the \( F \)-nibble lemma (Lemma 6.5) and the definition of a cleaner to each set \( U_i \) in the vortex.

**Proof of Lemma 7.5.** Choose new constants \( \gamma, \nu > 0 \) such that

\[ 1/m \ll 1/k \ll \gamma \ll \varepsilon \ll \nu \ll \mu \ll \xi, 1/f. \]

Apply Lemma 7.15 to obtain a \((\gamma, \nu, \kappa, F)\)-cleaner \( H_1, \ldots, H_\ell \). Note that by (V4) and Fact 7.2(ii), \( G[U_i] \) is an \((\varepsilon, \xi, f, r)\)-supercomplex for all \( i \in [\ell] \), and the same holds for \( i = 0 \) by assumption. Let \( H_{\ell+1} := \emptyset \) and \( U_{\ell+1} := \emptyset \).

For \( i \in [\ell] \), define the following conditions:

- (FP1*), \( F_i^* \) is a \( 4\kappa \)-well separated \( F \)-packing in \( G - H_{i+1} - G^{(r)}[U_{i+1}] \);
- (FP2*), \( F_i^* \) covers all edges of \( G^{(r)} \) that are not inside \( U_i \);
- (FP3*), for all \( e \in G^{(r)}[U_i] \), \( |F_i^*(e)| \leq 2\kappa \);
- (FP4*), \( \Delta(F_i^*(U_i)) \leq \mu|U_i| \).

Note that (FP1*)_{0} - (FP4*)_{0} hold trivially with \( F_0^* := \emptyset \). We will now proceed inductively until we obtain \( F_i^* \) satisfying (FP1*)_{\ell} - (FP4*)_{\ell}. Clearly, taking \( F := F_\ell^* \) completes the proof (using (FP1*)_{\ell} and (FP2*)_{\ell}).

Suppose that for some \( i \in [\ell] \), we have found \( F_{i-1} \) such that (FP1*)_{i-1} - (FP4*)_{i-1} hold. Let \( G_i := G[U_{i-1}] - (F_{i-1}^* \cup H_{i+1} \cup G^{(r)}[U_{i+1}]) - F_{i-1}^{* \leq (r+1)} \).

We now intend to find \( F_i \) such that:

- (FP1) \( F_i \) is a \( 2\kappa \)-well separated \( F \)-packing in \( G_i \);
(FP2) \( \mathcal{F}_i \) covers all edges from \( G^{(r)}[U_{i-1}] - \mathcal{F}_i^{(r)} \) that are not inside \( U_i \);

(FP3) \( \Delta(\mathcal{F}_i^{(r)}[U_i]) \leq \mu|U_i| \).

We first observe that this is sufficient for \( \mathcal{F}_i^* := \mathcal{F}_i^{(r)} \cup \mathcal{F}_i \) to satisfy (FP1*)_i- (FP4*)_i. Note that \( \mathcal{F}_i^{(r)} \) and \( \mathcal{F}_i^{(r)} \) are edge-disjoint, and \( \mathcal{F}_i \) and \( \mathcal{F}_i^* \) are \((r+1)\)-disjoint by definition of \( G_i \). Together with (FP1*), this implies that \( \mathcal{F}_i^* \) is a well separated \( F \)-packing in \( G - H_{i+1} - G^{(r)}[U_{i+1}] \).

If \( e \in E(G) \), then \( |F^{(r)}(e)| = 0 \) and hence \( |F^{(r)}(e)| = |F^{(r)}(e)| \leq 4 \kappa. \) If \( e \subseteq U_{i-1}, \) then we have \( |F^{(r)}(e)| = |F^{(r)}(e)| + |F^{(r)}(e)| \leq 4 \kappa \) by (FP3*)_i- and (FP1). Thus, \( \mathcal{F}_i^* \) is \( 4 \kappa \)-well separated and (FP1*)_i holds.

Clearly, (FP2*)_i- and (FP2) imply (FP2*). Moreover, observe that \( \mathcal{F}_i^{(r)}[U_i] \) is empty by (FP1*)_i-1. Thus, (FP3*)_i holds since \( \mathcal{F}_i \) is \( 2 \kappa \)-well separated, and (FP3) implies (FP4*).

It thus remains to show that \( \mathcal{F}_i \) satisfying (FP1)-(FP3) exists. We will obtain \( \mathcal{F}_i \) as the union of two packings, one obtained from the \( F \)-nibble lemma (Lemma 6.5) and one using (C4). Let \( G_{i,nibble} := G[U_{i-1}] - (F_{i-1}^{(r)} \cup H_i \cup G^{(r)}[U_i]) - F^{(r)}_{i-1}. \) Recall that \( G[U_{i-1}] \) is an \((\varepsilon, \xi, f, r)\)-supercomplex. In particular, it is \((\varepsilon, d, f, r)\)-regular for some \( d \geq \xi, \) and \( (\xi, f + r, r)\)-dense. Note that by (FP4*)_i-2, (C2) and (V2) we have

\[
\Delta(\mathcal{F}_i^{(r)}[U_{i-1}] \cup H_i \cup G^{(r)}[U_i]) \leq \mu|U_{i-1}| + \nu|U_{i-1}| + |U_{i-1}| \leq 3 \mu|U_{i-1}|
\]

Moreover, \( \Delta(\mathcal{F}_i^{(r)}(r+1)) \leq 4 \kappa(f - r) \leq \mu|U_{i-1}| \) by Fact 5.4(i). Thus, Proposition 5.9(i) and (ii) imply that \( G_{i,nibble} \) is still \((2 \mu, \xi, d, f, r)\)-regular and \((\xi/2, f + r, r)\)-dense. Since \( \mu \ll \xi, \) we can apply Lemma 6.5 to obtain a \( \kappa \)-well separated \( F \)-packing \( \mathcal{F}_{i,nibble} \) in \( G_{i,nibble} \) such that \( \Delta(L_{i,nibble}) \leq \frac{1}{2} \gamma|U_{i-1}| \), where \( L_{i,nibble} := G_{i,nibble} - F_{i,nibble} \).

Since (FP2*),

\[
G^{(r)} - F_{i-1}^{(r)} - F_{i,nibble}^{(r)} = G^{(r)}[U_{i-1}] - F_{i-1}^{(r)} - F_{i,nibble}^{(r)}
\]

\[
= (G_{i,nibble} \cup H_i \cup G^{(r)}[U_i]) - F_{i,nibble}^{(r)}
\]

\[
= H_i \cup G^{(r)}[U_i] \cup L_{i,nibble},
\]

we know that \( H_i \cup G^{(r)}[U_i] \cup L_{i,nibble} \) is \( F \)-divisible. By (C1) and (C3), we know that \( H_{i+1} \cup G^{(r)}[U_{i+1}] \subseteq G^{(r)}[U_i] - H_i. \) Moreover, by (C2) and Proposition 5.9(v) we have that \( G[U_i] - H_i \) is a \((2 \mu, \xi/2, f, r)\)-supercomplex. We can thus apply Corollary 6.10 (with \( G[U_i] - H_i, H_{i+1} \cup G^{(r)}[U_{i+1}], \)

\( 2 \mu \) playing the roles of \( G, H, \varepsilon \) to find an \( F \)-divisible subgraph \( R_i \) of \( G^{(r)}[U_i] - H_i \) containing \( H_{i+1} \cup G^{(r)}[U_{i+1}] \) such that \( \Delta(L_{i,res}) \leq \frac{1}{2} \gamma|U_i| \), where \( L_{i,res} := G^{(r)}[U_i] - H_i - R_i \).

Let \( L_i := L_{i,nibble} \cup L_{i,res}. \) Clearly, \( L_i \subseteq G^{(r)}[U_{i-1}] \) and \( \Delta(L_i) \leq \gamma|U_{i-1}|. \) Note that

\[
H_i \cup L_i = (H_i \cup (G^{(r)}[U_i] - H_i) \cup L_{i,nibble}) - R_i = G^{(r)} - F_{i-1}^{(r)} - F_{i,nibble}^{(r)} - R_i
\]

is \( F \)-divisible. Moreover, \( \Delta(\mathcal{F}_i^{(r)}(r+1)) \cup F_{i,nibble}^{(r)}(r+1) \leq 5 \kappa(f - r) \) by Fact 5.4(i). Thus, by (C4) there exists a \( \kappa \)-well separated \( F \)-packing \( \mathcal{F}_{i,\text{clean}} \) in

\[
G_{i,\text{clean}} := G[H_i \cup L_i][U_{i-1}] - \mathcal{F}_i^{(r)}(r+1) - F_{i-1}^{(r)}(r+1)
\]

which covers all edges of \( H_i \cup L_i \) except possibly some inside \( U_i \).

We claim that \( \mathcal{F}_i := \mathcal{F}_{i,nibble} \cup \mathcal{F}_{i,\text{clean}} \) is the desired packing. Since \( \mathcal{F}_{i,nibble} \) and \( \mathcal{F}_{i,\text{clean}} \) are edge-disjoint and \( \mathcal{F}_{i,nibble} \) and \( \mathcal{F}_{i,\text{clean}} \) are \((r+1)\)-disjoint, we have that \( \mathcal{F}_i \) is a \( 2 \kappa \)-well separated \( F \)-packing by Fact 5.4(ii). Moreover, it is easy to see from (C1) that \( G_{i,nibble} \subseteq G_i. \) Crucially, since \( R_i \) was chosen to contain \( H_{i+1} \cup G^{(r)}[U_{i+1}], \) we have from (FP2*) that

\[
H_i \cup L_i \leq G^{(r)}[U_{i-1}] - R_i - F_{i-1}^{(r)} \subseteq G^{(r)}[U_{i-1}] - (F_{i-1}^{(r)} \cup H_{i+1} \cup G^{(r)}[U_{i+1}])
\]

and thus \( G_{i,\text{clean}} \subseteq G_i \) as well. Hence, (FP1) holds.

Clearly, \( \mathcal{F}_i \) covers all edges of \( G^{(r)}[U_{i-1}] - \mathcal{F}_i^{(r)} \) that are not inside \( U_i, \) thus (FP2) holds. Finally, since \( \mathcal{F}_{i,nibble} \) is empty, we have \( \Delta(\mathcal{F}_i^{(r)}[U_i]) \leq \Delta(H_i \cup L_i) \leq \nu|U_{i-1}| + \gamma|U_{i-1}| \leq \mu|U_i|, \) as needed for (FP3). \( \square \)
8. Absorbers

In this section we show that for any (divisible) r-graph H in a supercomplex G, we can find an ‘exclusive’ absorber r-graph A (as discussed in Section 1.7, one may think of H as a potential leftover from an approximate F-decomposition and A will be set aside earlier to absorb H into an F-decomposition). The following definition makes this precise. The main result of this section is Lemma 8.2, which constructs an absorber provided that F is weakly regular. Building on [7], we will construct absorbers as a concatenation of ‘transformers’ and special ‘canonical graphs’. The goal is to transform an arbitrary divisible r-graph H into a canonical graph. In the following subsection, we will construct transformers. In Section 8.2, we will prove the existence of suitable canonical graphs. We will prove Lemma 8.2 in Section 8.3.

**Definition 8.1 (Absorber).** Let F, H and A be r-graphs. We say that A is an F-absorber for H if A and H are edge-disjoint and both A and A ∪ H have an F-decomposition. More generally, if G is a complex and H ⊆ G(r), then A ⊆ G(r) is a κ-well separated F-absorber for H in G if A and H are edge-disjoint and there exist κ-well separated F-packings F₀ and F* in G such that F₀(r) = A and F*(r) = A ∪ H.

**Lemma 8.2 (Absorbing lemma).** Let 1/n < 1/κ ≪ 1/h, ε ≪ ξ, 1/f and r ∈ [f − 1]. Assume that (∗) is true for all i ∈ [r − 1]. Let F be a weakly regular r-graph on f vertices, let G be an (ε, ξ, f, r)-supercomplex on n vertices and let H be an F-divisible subgraph of G(r) with |H| ≤ h. Then there exists a κ-well separated F-absorber A for H in G with Δ(A) ≤ γn.

We now briefly discuss the case r = 1. We write V(F) = {x₁, ..., x_f} and can assume that F = \{\{x₁\}, ..., \{x_f\}\} for some \(t \in [f]\).

Assume first that \(H = \{e₁, ..., e_t\}\). Choose any f-set \(Q₀ \in G^{(f)}\) and write \(Q₀ = \{v₁, ..., v_f\}\). Let \(F₀ \) be a copy of F with vertex set \(Q₀\) such that \(F₀ = \{\{v₁\}, ..., \{v_f\}\}\). Now, for every \(i \in [t]\), choose a \(Q_i \in G^{(f)}(e_i) \cap G^{(f)}(\{v_i\})\) (cf. Fact 5.6). Choose these sets such that \(\bigcup H, Q₀, Q₁, Q₂\) are pairwise disjoint. For every \(i \in [t]\), let \(F_i\) and \(F'_i\) be copies of F such that \(V(F_i) = Q_i \cup e_i, V(F'_i) = Q_i \cup \{v_i\}\) and \(F_i \triangle F'_i = e_i, \{v_i\}\).

Now, let \(A := \bigcup_{i \in [t]} F_i\). Then \(F₀ := \{F₀, F₁, ..., F_t\}\) is a 1-well separated F-packing in G with \(F₀^{(1)} = A\), and \(F* := \{F₀, F₁, ..., F_t\}\) is a 1-well separated F-packing in G with \(F*(r) = A ∪ H\).

Thus, A is a 1 well-separated F-absorber for H in G. More generally, if H is any F-divisible 1-graph, then \(t | |H|\) subgraphs of size t and then find an absorber for each of these subgraphs (successively so that they are appropriately disjoint.)

Thus, for the remainder of this section, we will assume that \(r ≥ 2\).

8.1. Transformers. Roughly speaking, a transformer T can be viewed as transforming a given leftover graph H into a new leftover H’ (where we set aside T and H’ earlier).

**Definition 8.3 (Transformer).** Let F be an r-graph, G a complex and assume that \(H, H’ ⊆ G^{(r)}\).

A subgraph \(T ⊆ G^{(r)}\) is a κ-well separated (H, H’; F)-transformer in G if T is edge-disjoint from both H and H’ and there exist κ-well separated F-packings \(F\) and \(F’\) in G such that \(F(r) = T ∪ H\) and \(F’(r) = T ∪ H’\).

Our ‘Transforming lemma’ (Lemma 8.5) guarantees the existence of a transformer for H and H’ if H’ is obtained from H by ‘identifying’ vertices. To make this more precise, given a multi-r-graph H and \(x, x’ \in V(H)\), we say that x and x’ are identifiable if \(|H(\{x, x’\})| = 0\), that is, if identifying x and x’ does not create an edge of size less than r. (Identifying x and x’ means that we create a new vertex \(x^*\), replace all appearances of x, x’ in edges with \(x^*\), and delete x, x’.) For multi-r-graphs H and H’, we write \(H ≈ H’\) if there is a sequence \(H₀, ..., H_t\) of multi-r-graphs such that \(H₀ ≃ H, H_t\) is obtained from H’ by deleting isolated vertices, and for every \(i \in [t]\), there are two identifiable vertices x, x’ ∈ V(\(H_{i−1}\)) such that \(H_i\) is obtained from \(H_{i−1}\) by identifying x and x’.

If H and H’ are (simple) r-graphs and \(H ≈ H’\), we just write \(H ⇝ H’\) to indicate the fact that during the identification steps, only vertices \(x, x’ \in V(H_{i−1})\) with \(H_{i−1}(\{x\}) ∩ H_{i−1}(\{x’\}) = \emptyset\) were identified (i.e. if we did not create multiple edges).
Clearly, ≃ is a reflexive and transitive relation on the class of multi-\(r\)-graphs, and \(\sim\) is a reflexive and transitive relation on the class of \(r\)-graphs.

It is easy to see that \(H \sim H'\) if and only if there is an edge-bijective homomorphism from \(H\) to \(H'\) (see Proposition 8.4(i)). Given \(r\)-graphs \(H, H'\), a homomorphism from \(H\) to \(H'\) is a map \(\phi: V(H) \rightarrow V(H')\) such that \(\phi(e) \in H'\) for all \(e \in H\). Note that this implies that \(\phi\) is injective for all \(e \in H\). We let \(\phi(H)\) denote the subgraph of \(H'\) with vertex set \(\phi(V(H))\) and edge set \(\{\phi(e) : e \in H\}\). We say that \(\phi\) is edge-bijective if \(|\phi(H)| = |H'\|\). For two \(r\)-graphs \(H\) and \(H'\), we write \(H \xrightarrow{\phi} H'\) if \(\phi\) is an edge-bijective homomorphism from \(H\) to \(H'\).

We now record a few simple observations about the relation \(\sim\) for future reference.

**Proposition 8.4.** The following hold.

(i) \(H \sim H'\) if and only if there exists \(\phi\) such that \(H \xrightarrow{\phi} H'\).

(ii) Let \(H_1, H_1', \ldots, H_t, H_t'\) be \(r\)-graphs such that \(H_1, \ldots, H_t\) are \(\phi\)-disjoint and \(H_1', \ldots, H_t'\) are edge-disjoint and \(H_i \equiv H_i'\) for all \(i \in [t]\). Then
\[
H_1 + \cdots + H_t \sim H_1' \cup \cdots \cup H_t'.
\]

(iii) If \(H \sim H'\) and \(H\) is \(F\)-divisible, then \(H'\) is \(F\)-divisible.

The following lemma guarantees the existence of a transformer from \(H\) to \(H'\) if \(F\) is weakly regular and \(H \sim H'\). The proof relies inductively on the assertion of the main complex decomposition theorem (Theorem 4.7).

**Lemma 8.5** (Transforming lemma). Let \(1/n \ll 1/\kappa \ll \gamma, 1/h, \varepsilon \ll \xi, 1/f\) and \(2 \leq r < f\). Assume that \((\ast_i)\) is true for all \(i \in [r - 1]\). Let \(F\) be a weakly regular \(r\)-graph on \(f\) vertices, let \(G\) be an \((\varepsilon, \xi, f, r)\)-supercritical complex of order \(n\). Define \(L\) to be a weakly regular \((F, H')\)-transformer on \(F\) with equal size. By 'mirroring' this extension, we can also obtain an \((F, G)\)-transformer \(L\) which covers all edges of \(S \cup L\). By 'mirroring' this extension, we can also obtain an \((F, G)\)-transformer \(L\) which covers all edges of \(S \cup L\) (see Definition 8.8 and Proposition 8.9). To make this more precise, we introduce the following notation.

**Definition 8.6.** Let \(V\) be a set and let \(V_1, V_2\) be disjoint subsets of \(V\) having equal size. Let \(\phi: V_1 \rightarrow V_2\) be a bijection. For a set \(S \subseteq V \setminus V_2\), define \(\phi(S) := (S \setminus V_1) \cup \phi(S \cap V_1)\). Moreover, for an \(r\)-graph \(R\) with \(V(R) \subseteq V \setminus V_2\), we let \(\phi(R)\) be the \(r\)-graph on \(\phi(V(R))\) with edge set \(\{\phi(e) : e \in R\}\).

The following fact is easy to see.

**Fact 8.7.** Suppose that \(V, V_1, V_2\) and \(\phi\) are as above. Then the following hold for every \(r\)-graph \(R\) with \(V(R) \subseteq V \setminus V_2\):

(i) \(\phi(R) \cong R\);

(ii) If \(R = R_1 \cup \cdots \cup R_k\), then \(\phi(R) = \phi(R_1) \cup \cdots \cup \phi(R_k)\) and thus \(\phi(R_1) = \phi(R) - \phi(R_2) - \cdots - \phi(R_k)\).

The following definition is a two-sided version of Definition 7.8.

**Definition 8.8.** Let \(F\) be an \(r\)-graph, \(i \in [r - 1]\) and assume that \(S^* \in \binom{V(F)}{i}\) is such that \(F(S^*)\) is non-empty. Let \(G\) be a complex and assume that \(S_1, S_2 \in \binom{V(G)}{i}\) are disjoint and that a bijection \(\phi: S_1 \rightarrow S_2\) is given. Suppose that \(F'\) is a well separated \(F(S^*)\)-packing in \(G(S_1) \cap G(S_2)\). We
then define $S_1 \triangleleft \mathcal{F}' \triangleright S_2$ as follows: For each $F' \in \mathcal{F}'$ and $j \in \{1, 2\}$, let $F'_j$ be a copy of $F$ on vertex set $S_j \cup V(F')$ such that $F'_j(S_j) = F'$ and such that $\phi(F'_j) = F'_j$. Let

$$F_1 := \{ F'_1 : F' \in \mathcal{F}' \};$$

$$F_2 := \{ F'_2 : F' \in \mathcal{F}' \};$$

$$S_1 \triangleleft \mathcal{F}' \triangleright S_2 := (F_1,F_2).$$

The next proposition is proved using its one-sided counterpart, Proposition 7.9. As in Proposition 7.9, the notion of well separatedness (Definition 4.5) is crucial here.

**Proposition 8.9.** Let $F$, $r$, $i$, $S^*$, $G$, $S_1$, $S_2$ and $\phi$ be as in Definition 8.8. Suppose that $L \subseteq G(S_1)^{(r-i)} \cap G(S_2)^{(r-i)}$ and that $\mathcal{F}'$ is a $\kappa$-well separated $F(S^*)$-decomposition of $(G(S_1) \cap G(S_2))[L]$. Then the following hold for $(F_1,F_2) = S_1 \triangleleft \mathcal{F}' \triangleright S_2$:

(i) for $j \in \{2\}$, $F_j$ is a $\kappa$-well separated $F$-packing in $G$ with $\{e \in F_j^{(r)} : S_j \subseteq e \} = S_j \uplus L$;

(ii) $V(F_1^{(r)}) \subseteq V(G) \setminus S_2$ and $\phi(F_1^{(r)}) = F_2^{(r)}$.

**Proof.** Let $j \in \{2\}$. Since $(G(S_1) \cap G(S_2))[L] \subseteq G(S_j)$, we can view $F_j$ as $S_j \triangleleft \mathcal{F}'$ (cf. Definition 7.8). Moreover, since $(G(S_1) \cap G(S_2))[L]^{(r-i)} = L = G(S_j)[L]^{(r-i)}$, we can conclude that $\mathcal{F}'$ is a $\kappa$-well separated $F(S^*)$-decomposition of $G(S_j)[L]$. Thus, by Proposition 7.9, $F_j$ is a $\kappa$-well separated $F$-packing in $G$ with $\{e \in F_j^{(r)} : S_j \subseteq e \} = S_j \uplus L$.

Moreover, we have $V(F_1^{(r)}) \subseteq \bigcup_{F' \in \mathcal{F}'} V(F_1') \subseteq V(G) \setminus S_2$ and by Fact 8.7(ii)

$$\phi(F_1^{(r)}) = \phi\left( \bigcup_{F' \in \mathcal{F}'} F_1' \right) = \bigcup_{F' \in \mathcal{F}'} \phi(F_1') = \bigcup_{F' \in \mathcal{F}'} F_2' = F_2^{(r)}.$$ 

We now sketch the proof of Lemma 8.5. Suppose for simplicity that $H'$ is simply a copy of $H$, i.e. $H' = \phi(H)$ where $\phi$ is an isomorphism from $H$ to $H'$. We aim to construct an $(H,H';\phi)$-transformer. In a first step, for every edge $e \in H$, we introduce a set $X_e$ of $V(F) - r$ new vertices and let $F_e$ be a copy of $F$ such that $V(F_e) = e \uplus X_e$ and $e \in F_e$. Let $T_1 := \bigcup_{e \in H} F_e[X_e]$ and $R_1 := \bigcup_{e \in H} F_e - T_1 - H$. Clearly, $\{F_e : e \in H\}$ is an $F$-decomposition of $H \uplus R_1 \uplus T_1$. By Fact 8.7(ii), we also have that $\{\phi(F_e) : e \in H\}$ is an $F$-decomposition of $H' \uplus \phi(\phi(R_1)) \uplus T_1$. Hence, $T_1$ is an $(H \uplus R_1, H' \uplus \phi(\phi(R_1)) ; F)$-transformer. Note that at this stage, it would suffice to find an $(R_1, \phi(\phi(R_1)) ; F)$-transformer $T_3$, as then $T_1 \uplus T_2 \uplus R_1 \uplus \phi(\phi(R_1))$ would be an $(H, H' ; F)$-transformer. The crucial difference now to the original problem is that every edge of $R_1$ contains at most $r - 1$ vertices from $V(H)$. On the other hand, every edge in $R_1$ contains at least one vertex in $V(H)$ as otherwise it would belong to $T_1$. We view this as Step 1 and will now proceed inductively. After Step $i$, we will have an $r$-graph $R_i$ and an $(H \uplus R_i, H' \uplus \phi(\phi(R_i)) ; F)$-transformer $T_i$ such that every edge $e \in R_i$ satisfies $1 \leq |e \cap V(H)| \leq r - i$. Thus, after Step $r$ we can terminate the process as $R_r$ must be empty and thus $T_r$ is an $(H, H' ; F)$-transformer.

In Step $i+1$, where $i \in \{r - 1\}$, we use $(*)_i$ inductively as follows. Let $R'_i$ consist of all edges of $R_i$ which intersect $V(H)$ in $r - i$ vertices. We decompose $R'_i$ into ‘local’ parts. For every edge $e \in R'_i$, there exists a unique set $S \in \binom{V(H)}{r-i}$ such that $e \subseteq S$. For each $S \in \binom{V(H)}{r-i}$, let $L_S := R'_i(S)$. Note that the ‘local’ parts $S \uplus L_S$ form a decomposition of $R'_i$. The problem of finding $R_{i+1}$ and $T_{i+1}$ can be reduced to finding a ‘localised transformer’ between $S \uplus L_S$ and $\phi(S) \uplus L_S$ for every $S$, as described above. At this stage, by Proposition 5.3, $L_S$ will automatically be $F(S^*)$-divisible, where $S^* \in \binom{V(F)}{r-i}$ is such that $F(S^*)$ is non-empty. If we were given an $F(S^*)$-decomposition $F_S$ of $L_S$, we could use Proposition 8.9 to extend $F_S$ to an $F$-packing $F_S$ which covers all edges of $S \uplus L_S$, and all new edges created by this extension intersect $S$ (and $V(H)$) in at most $r - i - 1$ vertices, as desired. It is possible to combine these localised transformers with $T_i$ and $R_i$ in such a way that we obtain $T_{i+1}$ and $R_{i+1}$.

Unfortunately, $(G(S) \cap G(\phi(S)))[L_S]$ might not be a supercomplex (one can think of $L_S$ as some leftover from previous steps) and so $F_S$ may not exist. However, by Proposition 5.5, we have that $G(S) \cap G(\phi(S))$ is a supercomplex. Thus we can (randomly) choose a suitable $i$-subgraph
A_{S} of \((G(S) \cap G(\phi(S)))^{(i)}\) such that \(A_{S}\) is \(F(S^{*})\)-divisible and edge-disjoint from \(L_S\). Instead of building a localised transformer for \(L_S\) directly, we will now build one for \(A_{S}\) and one for \(A_{S} \cup L_S\), using \((*)_i\) both times to find the desired \(F(S^{*})\)-decomposition. These can then be combined into a localised transformer for \(L_S\).

**Lemma 8.10.** Let \(1/n < \gamma' \ll 1/\kappa, \varepsilon \ll \xi, 1/f\) and \(1 \leq i < r < f\). Assume that \((*)_r-i\) is true. Let \(F\) be a weakly regular \(r\)-graph on \(f\) vertices and assume that \(S^{*} \in \left(V(F)^{r}\right)\) is such that \(F(S^{*})\) is non-empty. Let \(G\) be an \((\varepsilon, \xi, f, r, \gamma')\)-supercomplex on \(n\) vertices, let \(S_1, S_2 \in G^{(i)}\) with \(S_1 \cap S_2 = \emptyset\), and let \(\phi \colon S_1 \to S_2\) be a bijection. Moreover, suppose that \(L\) is an \(F(S^{*})\)-divisible 

Then there exist \(T, R \subseteq G^{(r)}\) such that the following hold:

- \((TR1)\) \(V(R) \subseteq V(G) \setminus S_2\) and \(e \cap S_1 \in [i - 1]\) for all \(e \in R\) (so if \(i = 1\), then \(R\) must be empty since \([0] = \emptyset\));
- \((TR2)\) \(T\) is a \((\kappa + 1)\) well-separated \(((S_1 \cup L) \cup (\phi(R), (S_2 \cup L) \cup R); F)\)-transformer in \(G\);
- \((TR3)\) \(|V(T \cup R)| \leq \gamma n\).

**Proof.** We may assume that \(\gamma' \ll \gamma \ll 1/\kappa, \varepsilon\). Choose \(\mu > 0\) with \(\gamma' \ll \mu \ll \gamma \ll 1/\kappa, \varepsilon\).

We split the argument into two parts. First, we will establish the following claim, which is the essential part and relies on \((*)_r-i\).

**Claim 1:** There exist \(T, R_{1,A}, R_{1,A\cup L} \subseteq G^{(r)}\) and \(\kappa\)-well separated \(G^{(r)}\)-packings \(F_{1}, F_{2}\) in \(G\) such that the following hold:

- \((tr1)\) \(V(T, R_{1,A} \cup R_{1,A\cup L}) \subseteq V(G) \setminus S_2\) and \(e \cap S_1 \in [i - 1]\) for all \(e \in R_{1,A} \cup R_{1,A\cup L}\);
- \((tr2)\) \(T, S_1 \cup L, S_2 \cup L, R_{1,A}, \phi(R_{1,A}), R_{1,A\cup L}, \phi(R_{1,A\cup L})\) are pairwise edge-disjoint subgraphs of \(G^{(r)}\);
- \((tr3)\) \(F_{1}'^{(r)} = T \cup (S_1 \cup L) \cup R_{1,A\cup L} \cup \phi(R_{1,A})\) and \(F_{2}'^{(r)} = T \cup (S_2 \cup L) \cup R_{1,A} \cup \phi(R_{1,A\cup L})\);
- \((tr4)\) \(|V(T \cup R_{1,A} \cup R_{1,A\cup L})| \leq 2\mu n\).

**Proof of claim:** By Corollary 5.17 and Lemma 5.10(i), there exists a subset \(U \subseteq V(G)\) with \(0.9\mu n \leq |U| \leq 1.1\mu n\) such that \(G' \coloneqq G[U \cup S_1 \cup S_2 \cup V(L)]\) is a \((2\varepsilon, \xi - \varepsilon, f, r)\)-supercomplex. By Proposition 5.5, \(G'' \coloneqq G'(S_1) \cap G'(S_2)\) is a \((2\varepsilon, \xi - \varepsilon, f - i, r - i)\)-supercomplex. Clearly, \(L \subseteq G''^{(r-i)}\) and \(\Delta(L) \leq \gamma' n \leq \sqrt{n}|U|\). Thus, by Proposition 5.9(v), \(G''^{r-i}\) is a \((3\varepsilon, \xi - 2\varepsilon, f - i, r - i)\)-supercomplex.

By Corollary 6.10, there exists \(A \subseteq G''^{(r-i) - L}\) such that \(A := G''^{(r-i) - L - H}\) is \(F(S^{*})\)-divisible and \(\Delta(H) \leq \gamma' n\). In particular, by Proposition 5.9(v) we have that

- \((i)\) \(G''[A]\) is an \(F(S^{*})\)-divisible \((3\varepsilon, \xi/2, f - i, r - i)\)-supercomplex;
- \((ii)\) \(G''[A \cup L]\) is an \(F(S^{*})\)-divisible \((3\varepsilon, \xi/2, f - i, r - i)\)-supercomplex.

Recall that \(F\) being weakly regular implies that \(F(S^{*})\) is weakly regular as well (see Proposition 5.3). By \((i)\) and \((*)_r-i\), there exists a \(\kappa\)-well separated \(F(S^{*})\)-decomposition \(F_{A}\) of \(G''[A]\).

By Fact 5.4(ii), \(\Delta(F_{A}^{(r-i-1)}) \leq \kappa f\). Thus, by \((ii)\), Proposition 5.9(v) and \((*)_r-i\), there also exists a \(\kappa\)-well separated \(F'(S^{*})\)-decomposition \(F_{A\cup L}\) of \(G''[A \cup L]\) \(- F_{A}^{(r-i-1)}\). In particular, \(F_{A}\) and \(F_{A\cup L}\) are \((r - i + 1)\)-disjoint.

We define

\[
(F_{1,A}, F_{2,A}) := S_1 \triangle F_{A} > S_2,
\]

\[
(F_{1,A\cup L}, F_{2,A\cup L}) := S_1 \triangle F_{A\cup L} > S_2.
\]

By Proposition 8.9(i), for \(j \in \{2\}, F_{j,A}\) is a \(\kappa\)-well separated \(F\)-packing in \(G' \subseteq G\) with \(e \in F_{j,A}^{(r)}: S_j \subseteq e = S_j \cup A\) and \(F_{j,A\cup L}\) is a \(\kappa\)-well separated \(F\)-packing in \(G' \subseteq G\) with \(e \in F_{j,A\cup L}^{(r)}: S_j \subseteq e = S_j \cup (A \cup L)\).
For \( j \in [2] \), let

\[
T_{j,A} := \{ e \in F_{j,A}^{(r)} : |e \cap S_j| = 0 \},
\]

\[
T_{j,A,U,L} := \{ e \in F_{j,A,U,L}^{(r)} : |e \cap S_j| = 0 \},
\]

\[
R_{j,A} := \{ e \in F_{j,A,U,L}^{(r)} : |e \cap S_j| \in \{ i - 1 \} \},
\]

\[
R_{j,A,U,L} := \{ e \in F_{j,A,U,L}^{(r)} : |e \cap S_j| \in \{ i - 1 \} \}.
\]

By Definition 8.8, we have that \( T_{1,A} = T_{2,A} \) and \( T_{1,A,U,L} = T_{2,A,U,L} \). We thus set

\[
T_A := T_{1,A} = T_{2,A} \quad \text{and} \quad T_{A,U,L} := T_{1,A,U,L} = T_{2,A,U,L}.
\]

Moreover, we have

\[
(8.1) \quad \phi(R_{1,A}) = R_{2,A} \quad \text{and} \quad \phi(R_{1,A,U,L}) = R_{2,A,U,L}.
\]

Note that \( R_{1,A}, R_{2,A}, R_{1,A,U,L}, R_{2,A,U,L} \) are empty if \( i = 1 \). Crucially, since \( F_A \) and \( F_{A,U,L} \) are \((r - i + 1)\)-disjoint, it is easy to see (by contradiction) that \( T_A \) and \( T_{A,U,L} \) are edge-disjoint, and that for \( j \in [2] \), \( R_{j,A} \) and \( R_{j,A,U,L} \) are edge-disjoint. Further, since \( A \) and \( L \) are edge-disjoint, we clearly have for \( j \in [2] \) that \( S_j \subseteq L \) and \( S_j \subseteq A \) are edge-disjoint. Using this, it is straightforward to see that

\( \{\} \) \( S_1 \subseteq L \), \( S_2 \subseteq L \), \( S_1 \subseteq A \), \( S_2 \subseteq A \), \( T_A \), \( T_{A,U,L} \), \( R_{1,A} \), \( R_{2,A} \), \( R_{1,A,U,L} \), \( R_{2,A,U,L} \) are pairwise edge-disjoint subgraphs of \( G^{(r)} \).

Observe that for \( j \in [2] \), we have

\[
(8.2) \quad F_{j,A}^{(r)} = (S_j \cup A) \cup R_{j,A} \cup T_A;
\]

\[
(8.3) \quad F_{j,A,U,L}^{(r)} = (S_j \cup (A \cup L)) \cup R_{j,A,U,L} \cup T_{A,U,L}.
\]

Define

\[
\hat{T} := (S_1 \cup A) \cup (S_2 \cup A) \cup T_A \cup T_{A,U,L};
\]

\[
\hat{F}_1 := F_{1,A,U,L} \cup F_{2,A};
\]

\[
\hat{F}_2 := F_{1,A} \cup F_{2,A,U,L}.
\]

We now check that (tr1)–(tr4) hold. First note that by (\{\}) we clearly have \( \hat{T}, R_{1,A}, R_{1,A,U,L} \subseteq G^{(r)} \).

Moreover, since \( F_A \) and \( F_{A,U,L} \) are \((r - i + 1)\)-disjoint, we have that \( F_{1,A,U,L} \) and \( F_{2,A} \) are \( r \)-disjoint and thus \( \hat{F}_1 \) is a \( \kappa \)-well separated \( F \)-packing in \( G \) by Fact 5.4(iii). Similarly, \( \hat{F}_2 \) is a \( \kappa \)-well separated \( F \)-packing in \( G \).

To check (tr1), note that \( V(R_{1,A}) \subseteq V(F_{1,A}^{(r)}) \subseteq V(G) \setminus S_2 \) and \( V(R_{1,A,U,L}) \subseteq V(F_{1,A,U,L}^{(r)}) \subseteq V(G) \setminus S_2 \) by Proposition 8.9(ii). Moreover, for all \( e \in R_{1,A} \cup R_{1,A,U,L} \), we have \( |e \cap S_1| \in \{ i - 1 \} \) by definition. Hence, (tr1) holds. Clearly, (8.1) and (\{\}) imply (tr2). Crucially, by (8.1)–(8.3) we have that

\[
\hat{F}_1^{(r)} = F_{1,A,U,L}^{(r)} \cup F_{2,A}^{(r)} = \hat{T} \cup (S_1 \cup L) \cup R_{1,A,U,L} \cup \phi(R_{1,A});
\]

\[
\hat{F}_2^{(r)} = F_{1,A}^{(r)} \cup F_{2,A,U,L}^{(r)} = \hat{T} \cup (S_2 \cup L) \cup R_{1,A} \cup \phi(R_{1,A,U,L}).
\]

Thus, (tr3) is satisfied. Finally, \( |V(\hat{T} \cup R_{1,A} \cup R_{1,A,U,L})| \leq |V(G')| \leq 2n \), proving the claim.

The transformer \( \hat{T} \) almost has the required properties, except that to satisfy (TR2) we would have needed \( R_{1,A,U,L} \) and \( \phi(R_{1,A,U,L}) \) to be on the ‘other side’ of the transformation. In order to resolve this, we carry out an additional transformation step. (Since \( R_{1,A} \) and \( R_{1,A,U,L} \) are empty if \( i = 1 \), this additional step is vacuous in this case.)

\begin{itemize}
  \item[Claim 2:] There exist \( T', R' \subseteq G^{(r)} \) and 1-well separated \( F \)-packings \( \hat{F}_1, \hat{F}_2 \) in \( G - \hat{F}_1^{(r+1)} - \hat{F}_2^{(r+1)} \) such that the following hold:
  \begin{enumerate}
    \item[(tr1')] \( V(R') \subseteq V(G) \setminus S_2 \) and \( |e \cap S_1| \in \{ i - 1 \} \) for all \( e \in R' \);
    \item[(tr2')] \( T', R', \phi(R'), \hat{T}, S_1 \cup L, S_2 \cup L, R_{1,A}, \phi(R_{1,A}), R_{1,A,U,L}, \phi(R_{1,A,U,L}) \) are pairwise edge-disjoint \( r \)-graphs;
  \end{enumerate}
\end{itemize}
(tr3') \( F_1^{(r)} = T' \cup R_{1,AUL} \cup R' \) and \( F_2^{(r)} = T' \cup \phi(R_{1,AUL}) \cup \phi(R'); \\
(tr4') |V(T' \cup R')| \leq 0.7\gamma n.

**Proof of claim:** Let \( H' := \hat{T} \cup R_{1,A} \cup \phi(R_{1,A}) \cup (S_1 \cup L) \cup (S_2 \cup L). \) Clearly, \( \Delta(H') \leq 5\mu n. \)

Let \( W := V(R_{1,AUL}) \cup V(\phi(R_{1,AUL})). \) By (tr4), we have that \(|W| \leq 4\mu n. \) Similarly to the beginning of the proof of Claim 1, by Corollary 5.17 and Lemma 5.10(i), there exists a subset \( U' \subseteq V(G) \) with \( 0.4\gamma n \leq |U'| \leq 0.6\gamma n \) such that \( G'' := G[U' \cup W] \) is a \((2\varepsilon, \xi, \varepsilon, f, r)\)-supercomplex. Let \( \bar{n} := |U' \cup W|. \) Note that

\[
\Delta(H') \leq 5\mu n \leq \sqrt{\bar{n}} \quad \text{and} \quad \Delta(\tilde{F}_j^{(r)}(r+1)) \leq \kappa(f-r)
\]

for \( j \in [2] \) by Fact 5.4(i). Thus, by Proposition 5.9(v),

\[
\tilde{G} := G'' - H' - \tilde{F}_j^{(r+1)} - \tilde{F}_2^{(r+1)}
\]

is still a \((3\varepsilon, \xi, 2\varepsilon, f, r)\)-supercomplex. For every \( e \in R_{1,AUL}, \)

\[
Q_e := \{ \tilde{Q} \in \tilde{G}^{(f)}(e) \cap \tilde{G}^{(f)}(\phi(e)) : Q \cap (S_1 \cup S_2) = \emptyset \}.
\]

By Fact 5.6, for every \( e \in R_{1,AUL} \subseteq \tilde{G}^{(r)}, \) we have that \( |\tilde{G}^{(f)}(e) \cap \tilde{G}^{(f)}(\phi(e))| \geq 0.5\xi \tilde{n}^{f-r}. \) Thus, we have that \( |Q_e| \geq 0.4\xi \tilde{n}^{f-r}. \) Thus, \Delta(\tilde{R}_{1,AUL} \cup \phi(R_{1,AUL})) \leq 4\mu n \leq \sqrt{\bar{n}} \), we can apply Lemma 6.7 (with \( \tilde{R}_{1,AUL} = \tilde{R}, \tilde{e} = \phi(e) \)), \( Q_e \) playing the roles of \( m, s, L_j, \tilde{Q}_j \) to find for every \( e \in R_{1,AUL} \) some \( Q_e \in Q_e \) such that, writing \( K_e := (Q_e \cup \{ \phi(e) \})^{\bar{X}}, \)

we have that

\[
|Q_e| \geq 0.4\xi \tilde{n}^{f-r}.
\]

For each \( e \in R_{1,AUL}, \) let \( \tilde{F}_{e,1} \) and \( \tilde{F}_{e,2} \) be copies of \( F \) with \( V(\tilde{F}_{e,1}) = e \cup Q_e \) and \( V(\tilde{F}_{e,2}) = \phi(e) \cup Q_e \) and such that \( e \in \tilde{F}_{e,1} \) and \( \phi(e) \in \tilde{F}_{e,2} \). Clearly, we have that \( e \in \tilde{F}_{e,1} \). Moreover, since \( e \subseteq V(R_{1,AUL}) \subseteq V(G) \setminus S_2 \) by (tr1) and \( Q_e \cap (S_1 \cup S_2) = \emptyset, \) we have \( \tilde{V}(\tilde{F}_{e,1}) \subseteq V(G) \setminus S_2 \). Let

\[
F_1' := \{ \tilde{F}_{e,1} : e \in R_{1,AUL} \};
\]

\[
F_2' := \{ \tilde{F}_{e,2} : e \in R_{1,AUL} \}.
\]

By (8.4), \( F_1' \) and \( F_2' \) are both 1-well separated \( F \)-packings in \( \tilde{G} \subseteq G - \tilde{F}_j^{(r+1)} - \tilde{F}_2^{(r+1)} \). Moreover, \( V(F_1^{(r)}) \subseteq V(G) \setminus S_2 \) and \( \phi(F_1^{(r)}) = F_2^{(r)} \). Let

\[
T' := F_1^{(r)} \cap F_2^{(r)};
\]

\[
R' := F_1^{(r)} - T' - R_{1,AUL}.
\]

We clearly have \( T', R' \subseteq G^{(r)} \) and now check (tr1')–(tr4'). Note that no edge of \( T' \) intersects \( S_1 \cup S_2. \) For (tr1'), we first have that \( V(R') \subseteq V(F_1^{(r)}) \subseteq V(G) \setminus S_2. \) Now, consider \( e' \in R'. \) There exists \( e' \in R_{1,AUL} \) with \( e' \in \tilde{F}_{e,1} \) and thus \( e' \subseteq e \cup Q_e. \) If we had \( e' \cap S_1 = \emptyset, \) then \( e' \subseteq (e \setminus S_1) \cup Q_e. \) Since \( \phi(\tilde{F}_{e,1}) = \tilde{F}_{e,2}, \) it follows that \( e' \in T', \) a contradiction to (8.8). Hence, \( |e' \cap S_1| > 0. \) Moreover, by (tr1) we have \( |e' \cap S_1| \leq |e \cup Q_e | \cap S_1 | = |e \cap S_1 | \leq i - 1. \) Therefore, \( |e' \cap S_1 | \in [i - 1] \) and (tr1') holds.

In order to check (tr3'), observe first that by (8.8) and (8.5), we have \( F_1^{(r)} = T' \cup R_{1,AUL} \cup R'. \) Hence, by Fact 8.7(ii), we have

\[
F_2^{(r)} = \phi(F_1^{(r)}) = \phi(T') \cup \phi(R_{1,AUL}) \cup \phi(R') = T' \cup \phi(R_{1,AUL}) \cup \phi(R'),
\]

so (tr3') is satisfied.

We now check (tr2'). Note that \( T', R', \phi(R') \subseteq \tilde{G}^{(r)} \subseteq G^{(r)} - H'. \) Thus, by (tr2), it is enough to check that \( T', R', \phi(R'), R_{1,AUL}, \phi(R_{1,AUL}) \) are pairwise edge-disjoint. Recall that no edge of \( T' \) intersects \( S_1 \cup S_2. \) Moreover, for every \( e \in R' \cup R_{1,AUL}, \) we have \( |e \cap S_1| \in [i - 1] \) and \( e \cap S_2 = \emptyset, \) and for every \( e \in \phi(R') \cup \phi(R_{1,AUL}), \) we have \( |e \cap S_2| \in [i - 1] \) and \( e \cap S_1 = \emptyset. \) Since \( R' \) and \( R_{1,AUL} \) are edge-disjoint by (8.8) and \( \phi(R') \) and \( \phi(R_{1,AUL}) \) are edge-disjoint by (8.9), this implies that \( T', R', \phi(R'), R_{1,AUL}, \phi(R_{1,AUL}) \) are indeed pairwise edge-disjoint, proving (tr2').

Finally, we can easily check that \(|V(T' \cup R')| \leq \bar{n} \leq 0.7\gamma n. \)
We now combine the results of Claims 1 and 2. Let
\[
T := \hat{T} \cup R_{1,AUL} \cup \phi(R_{1,AUL}) \cup T';
\]
\[
R := R_{1,A} \cup R';
\]
\[
\mathcal{F}_1 := \hat{\mathcal{F}}_1 \cup \mathcal{F}_2';
\]
\[
\mathcal{F}_2 := \hat{\mathcal{F}}_2 \cup \mathcal{F}_1'.
\]

Clearly, (tr1) and (tr1') imply that (TR1) holds. Moreover, (tr2') implies that \(T\) is edge-disjoint from both \((S_1 \uplus L) \cup \phi(R)\) and \((S_2 \uplus L) \cup R\). Using (tr3) and (tr3'), observe that
\[
T \cup (S_1 \uplus L) \cup \phi(R) = \hat{T} \cup R_{1,AUL} \cup \phi(R_{1,AUL}) \cup T' \cup (S_1 \uplus L) \cup \phi(R_{1,A}) \cup \phi(R')
\]
\[
= (\hat{T} \cup (S_1 \uplus L) \cup R_{1,AUL} \cup \phi(R_{1,A})) \cup (T' \cup \phi(R_{1,AUL}) \cup \phi(R'))
\]
\[
= \hat{\mathcal{F}}_1^{(r)} \cup \mathcal{F}_2^{(r)} = \mathcal{F}_1^{(r)}.
\]
Similarly, \(\mathcal{F}_2^{(r)} = \hat{\mathcal{F}}_2^{(r)} \cup \mathcal{F}_1^{(r)} = T \cup (S_2 \uplus L) \cup R\). In particular, by Fact 5.4(ii) we can see that \(\mathcal{F}_1\) and \(\mathcal{F}_2\) are \((k + 1)\)-well separated \(\mathcal{F}\)-packings in \(G\). Thus, \(T\) is a \((k + 1)\)-well separated \(((S_1 \uplus L) \cup \phi(R), (S_2 \uplus L) \cup R; F)\)-transformer in \(G\), so (TR2) holds. Finally, we have \(|V(T \cup R)| \leq 4\mu n + 0.7\gamma n \leq \gamma n\) by (tr4) and (tr4').

So far, our maps \(\phi: S_1 \to S_2\) were bijections. When \(\phi\) is an edge-bijective homomorphism from \(H\) to \(H'\), \(\phi\) is in general not injective. In order to still have a meaningful notion of `mirroring' as before, we introduce the following notation.

**Definition 8.11.** Let \(V\) be a set and let \(V_1, V_2\) be disjoint subsets of \(V\), and let \(\phi: V_1 \to V_2\) be a map. For a set \(S \subseteq V \setminus V_2\), define \(\phi(S) := (S \setminus V_1) \cup \phi(S \cap V_1)\). Let \(r \in \mathbb{N}\) and suppose that \(R\) is an \(r\)-graph with \(V(R) \subseteq V\) and \(i \in [r]_0\). We say that \(R\) is \((\phi, V, V_1, V_2, i)\)-projectable if the following hold:

(Y1) for every \(e \in R\), we have that \(e \cap V_2 = \emptyset\) and \(|e \cap V_1| \in [i]\) (so if \(i = 0\), then \(R\) must be empty since \([0] = \emptyset\));

(Y2) for every \(e \in R\), we have \(|\phi(e)| = r\);

(Y3) for every two distinct edges \(e, e' \in R\), we have \(\phi(e) \neq \phi(e')\).

Note that if \(\phi\) is injective and \(e \cap V_2 = \emptyset\) for all \(e \in R\), then (Y2) and (Y3) always hold. If \(R\) is \((\phi, V, V_1, V_2, i)\)-projectable, then let \(\phi(R)\) be the \(r\)-graph on \(\phi(V(R) \setminus V_2)\) with edge set \(\{\phi(e) : e \in R\}\). For an \(r\)-graph \(P\) with \(V(P) \subseteq V \setminus V_2\) that satisfies (Y2), let \(P^\phi\) be the \(r\)-graph on \(V(P) \cup V_1\) that consists of all \(e \in V_{r'}\) such that \(\phi(e) = \phi(e')\) for some \(e' \in P\).

The following facts are easy to see.

**Proposition 8.12.** Let \(V, V_1, V_2, \phi, R, r, i\) be as above and assume that \(R\) is \((\phi, V, V_1, V_2, i)\)-projectable. Then the following hold:

(i) \(R \leadsto \phi(R)\);

(ii) every subgraph of \(R\) is \((\phi, V, V_1, V_2, i)\)-projectable;

(iii) for all \(e' \in \phi(R)\), we have \(e' \cap V_1 = \emptyset\) and \(|e' \cap V_2| \in [i]\);

(iv) assume that for all \(e \in R\), we have \(|e \cap V_1| = i\), and let \(S\) contain all \(S \in \binom{V_1}{i}\) such that \(S\) is contained in some edge of \(R\), then
\[
R = \bigcup_{S \in S} (S \cup R(S)) \quad \text{and} \quad \phi(R) = \bigcup_{S \in S} (\phi(S) \cup R(S)).
\]

We can now prove the Transforming lemma by combining many localised transformers.

**Proof of Lemma 8.5.** We can assume that \(1/\kappa \ll \gamma \ll 1/h, \varepsilon\). Choose new constants \(\kappa' \in \mathbb{N}\) and \(\gamma_2, \ldots, \gamma_r, \gamma_2' \ldots, \gamma_r' > 0\) such that
\[
1/n \ll 1/\kappa \ll \gamma_2 \ll \gamma_2' \ll \gamma_{r-1} \ll \gamma_{r-1}' \ll \cdots \ll \gamma_2 \ll \gamma_2' \ll \gamma \ll 1/\kappa', 1/h, \varepsilon \ll \xi, 1/f.
\]
Let $\phi : V(H) \to V(H')$ be an edge-bijective homomorphism from $H$ to $H'$. Extend $\phi$ as in Definition 8.11 with $V(H), V(H')$ playing the roles of $V_1, V_2$. Since $\phi$ is edge-bijective, we have that

\begin{equation}
\phi|_S \text{ is injective whenever } S \subseteq e \text{ for some } e \in H.
\end{equation}

For every $e \in H$, we have $|G(G(f)) \cap G(G(f))(\phi(e))| \geq 0.5\xi_{n'-r}$ by Fact 5.6. It is thus easy to find for each $e \in H$ some $Q_e \in G(G(f)) \cap G(G(f))(\phi(e))$ with $Q_e \cap (V(H) \cup V(H')) = \emptyset$ such that $Q_e \cap Q_{e'} = \emptyset$ for all distinct $e, e' \in H$. For each $e \in H$, let $F_{e,1}$ and $F_{e,2}$ be copies of $F$ with $V(F_{e,1}) = e \cup Q_e$ and $V(F_{e,2}) = \phi(e) \cup Q_e$ and such that $e \in F_{e,1}$ and $\phi(F_{e,1}) = F_{e,2}$. Clearly, we have that $\phi(e) \in F_{e,2}$. For $j \in [2]$, define $F_{r,j} := \{F_{e,j} : e \in H\}$. Clearly, $F_{r,1}$ and $F_{r,2}$ are both 1-well separated $F$-packings in $G$. Define

\begin{align}
T^*_r := F^{(r)}_{r,1} \cap F^{(r)}_{r,2}, \\
R^*_r := F^{(r)}_{r,1} - T^*_r - H.
\end{align}

Let $\gamma_1 := \gamma$. Furthermore, let $\kappa_r := 1$ and recursively define $\kappa_i := \kappa_{i+1} + ((i))^\kappa'$ for all $i \in [r-1]$. Given $i \in [r - 1]_0$ and $T^*_{i+1}, R^*_{i+1}, F^*_{i+1,1}, F^*_{i+1,2}$, we define the following conditions:

(\text{TR1}^r), $T^*_{i+1}$ is $(\phi, V(G), V(H), V(H'), i)$-projectable;
(\text{TR2}^r), $T^*_{i+1}, R^*_{i+1}, \phi(R^*_{i+1}), H, H'$ are edge-disjoint subgraphs of $G^{(r)}$;
(\text{TR3}^r), $F^*_{i+1,1}$ and $F^*_{i+1,2}$ are $\kappa_{i+1}$-well separated $F$-packings in $G$ with $F^*_{i+1,1} = T^*_{i+1} \cup H \cup R^*_{i+1}$ and $F^*_{i+1,2} = T^*_{i+1} \cup H' \cup \phi(R^*_{i+1})$;
(\text{TR4}^r), $|V(T^*_{i+1} \cup R^*_{i+1})| \leq \gamma_1 + n$.

We will first show that the above choices of $T^*_r, R^*_r, F^*_r, F_{r,2}$ satisfy $(\text{TR1}^r)_{r-1} - (\text{TR4}^r)_{r-1}$. We will then proceed inductively until we obtain $T^*_1, R^*_1, F^*_1, F_{r,2}$ satisfying $(\text{TR1}^r)_0 - (\text{TR4}^r)_0$, which will then easily complete the proof.

 Claim 1: $T^*_r, R^*_r, F^*_r, F_{r,2}$ satisfy $(\text{TR1}^r)_{r-1} - (\text{TR4}^r)_{r-1}$.

\textbf{Proof of claim:} $(\text{TR4}^r)_{r-1}$ clearly holds. To see $(\text{TR1}^r)_{r-1}$, consider any $e' \in R^*_r$. There exists $e \in H$ such that $e' \subseteq e \cup Q_e$. In particular, $e' \subseteq V(H)$, then $e' = e \in H$, and if $e' \cap V(H) = \emptyset$, then $e' \in F_{e,2}$ since $\phi(F_{e,1}) = F_{e,2}$ and thus $e' \in T^*_r$. Hence, by definition of $R^*_r$, we must have $|e' \cap V(H)| \in [r - 1]$. Clearly, $e' \cap V(H') \subseteq (e \cup Q_e) \cap V(H') = \emptyset$, so $(\text{Y1})$ holds. Moreover, $e' \cap V(H) \subseteq e$, so $\phi(e') \cap V(H')$ is injective by \eqref{8.10}, and \eqref{Y2} holds. Let $e', e'' \in R^*_r$ and suppose that $\phi(e') = \phi(e'')$. We thus have $e' \cap V(H) = e'' \cap V(H) \neq \emptyset$. Since the $Q_e$s were chosen to be vertex-disjoint, we must have $e', e'' \subseteq e \cup Q_e$ for some $e \in H$. Hence, $(e' \cup e'') \cap V(H') \subseteq e$ and so $\phi((e' \cup e'') \cap V(H'))$ is injective by \eqref{8.10}. Since $\phi(e' \cap V(H)) = \phi(e' \cap V(H'))$ by assumption, we have $e' \cap V(H) = e'' \cap V(H)$, and thus $e' = e''$. Altogether, $(\text{Y3})$ holds, so $(\text{TR1}^r)_{r-1}$ is satisfied. In particular, $\phi(R^*_r)$ is well-defined. Observe that

\[ \phi(R^*_r) = F^{(r)}_{r,2} - T^*_r - H'. \]

Clearly, $T^*_r, R^*_r, \phi(R^*_r), H, H'$ are subgraphs of $G^{(r)}$. Using Proposition 8.12(iii), it is easy to see that they are indeed edge-disjoint, so $(\text{TR2}^r)$ holds. Moreover, note that $F^*_{r,1}$ and $F^*_{r,2}$ are 1-well separated $F$-packings in $G$ with $F^{(r)}_{r,1} = T^*_r \cup H \cup R^*_r$ and $F^{(r)}_{r,2} = T^*_r \cup H' \cup \phi(R^*_r)$, so $T^*_r$ satisfies $(\text{TR3}^r)_{r-1}$.

Suppose that for some $i \in [r - 1]$, we have already found $T^*_{i+1}, R^*_{i+1}, F^*_{i+1,1}, F^*_{i+1,2}$ such that $(\text{TR1}^i)_{i-1} - (\text{TR4}^i)_{i-1}$ hold. We will now find $T^*_i, R^*_i, F^*_i, F_{r,2}$ such that $(\text{TR1}^i)_{i-1} - (\text{TR4}^i)_{i-1}$ hold. To this end, let

\[ R_i := \{e \in R^*_{i+1} : |e \cap V(H)| = i\}. \]

By Proposition 8.12(ii), $R_i$ is $(\phi, V(G), V(H), V(H'), i)$-projectable. Let $S_i$ be the set of all $S \in (V(H))_i$ such that $S$ is contained in some edge of $R_i$. For each $S \in S_i$, let $L_S := R_i(S)$. By
Proposition 8.12(iv), we have that

\[(8.12) \quad R_i = \bigcup_{S \in S_i} (S \cup L_S) \quad \text{and} \quad \phi(R_i) = \bigcup_{S \in S_i} (\phi(S) \cup L_S).\]

We intend to apply Lemma 8.10 to each pair $S, \phi(S)$ with $S \in S_i$ individually. For each $S \in S_i$, define

\[V_S := (V(G) \setminus (V(H) \cup V(H'))) \cup S \cup \phi(S).\]

Claim 2: For every $S \in S_i$, $L_S \subseteq G[V_S](S)^{(r-i)} \cap G[V_S](\phi(S))^{(r-i)}$ and $|V(L_S)| \leq 1.1 \gamma_{i+1}|V_S|$. 

Proof of claim: The second assertion clearly holds by (TR4*). To see the first one, let $e' \in L_S = R_i(S)$. Since $R_i \subseteq R_{i+1}^{(r)} \subseteq G^{(r)}$, we have $e' \in G(S)^{(r-i)}$. Moreover, $\phi(S) \cup e' \subseteq \phi(R_i) \subseteq \phi(R_{i+1}^{(r)}) \subseteq G^{(r)}$ by (8.12). Since $R_{i+1}^r$ is $(\phi, V(G), V(H), V(H'), i)$-projectable, we have that $e' \cap (V(H) \cup V(H')) = \emptyset$. Thus, $S \cup e' \subseteq V_S$ and $\phi(S) \cup e' \subseteq V_S$. 

Let $S^* \in (V/F)$ be such that $F(S^*)$ is non-empty.

Claim 3: For every $S \in S_i$, $L_S$ is $F(S^*)$-divisible.

Proof of claim: Consider $b \in V(L_S)$ with $|b| < r - i$. We have to check that $\text{Deg}(F(S^*)|_S|_b | L_S(b))$. By (TR3*), both $T_{i+1}^r \cup H \cup R_{i+1}^r$ and $T_{i+1}^r \cup H^r \cup \phi(R_{i+1}^r)$ are necessarily $F$-divisible. Clearly, $H'$ does not contain an edge that contains $S$. Note that by (TR1*), and Proposition 8.12(iii), $\phi(R_{i+1}^r)$ does not contain an edge that contains $S$ either, hence $|T_{i+1}^r(S \cup b)| = |(T_{i+1}^r \cup H' \cup \phi(R_{i+1}^r))(S \cup b)| = 0 \mod \text{Deg}(F)|_S|_b$. Moreover, since $H$ is $F$-divisible, we have $|(T_{i+1}^r \cup R_{i+1}^r)(S \cup b)| \equiv |(T_{i+1}^r \cup H \cup R_{i+1}^r)(S \cup b)| \equiv 0 \mod \text{Deg}(F)|_S|_b$. Thus, we have $\text{Deg}(F)|_S|_b | |L_{i+1}^r(S \cup b)$. Moreover, $|R_{i+1}^r(S \cup b)| = |R_i(S \cup b)| = |L_S(b)|$. Hence, $\text{Deg}(F)|_S|_b | |L_S(b)|$, which proves the claim as $\text{Deg}(F)|_S|_b = \text{Deg}(F(S^*)|_S|_b)$ by Proposition 5.3.

We now intend to apply Lemma 8.10 for every $S \in S_i$, in order to define $T_S, R_S \subseteq G^{(r)}$ and $\kappa'$-well separated $F$-packings $F_{S,1}, F_{S,2}$ in $G$ such that the following hold:

(TR1') $R_S$ is $(\phi, V(G), V(H), V(H'), i - 1)$-projectable;

(TR2') $T_S, R_S, \phi(R_S), S \cup L_S, \phi(S) \cup L_S$ are edge-disjoint;

(TR3') $F_{S,1}^{(r)} = T_S \cup (S \cup L_S) \cup \phi(R_S)$ and $F_{S,2}^{(r)} = T_S \cup (\phi(S) \cup L_S) \cup R_S$;

(TR4') $|V(T_S \cup R_S)| \leq \gamma_{i+1}n$.

We also need to ensure that all these graphs and packings satisfy several ‘disjointness properties’ (see (a)–(c)), and we will therefore choose them successively. Recall that $P^\phi$ (for a given $r$-graph $P$) was defined in Definition 8.11. Let $S' \subseteq S_i$ be the set of all $S' \in S_i$ for which $T_{S'}, R_{S'}$ and $F'_{S',1}, F'_{S',2}$ have already been defined such that (TR1')–(TR4') hold. Suppose that next we want to find $T_S, R_S, F_{S,1}$ and $F_{S,2}$. Let

\[P_S := R_{i+1}^r \cup \bigcup_{S' \in S'} R_{S'},\]

\[M_S := T_{i+1}^r \cup R_{i+1}^r \cup \phi(R_{i+1}^r) \cup \bigcup_{S' \in S'} (T_{S'} \cup R_{S'} \cup \phi(R_{S'})),\]

\[O_S := F_{i+1,1}^{(r+1)} \cup F_{i+1,2}^{(r+1)} \cup \bigcup_{S' \in S'} F_{S',1}^{(r+1)} \cup F_{S',2}^{(r+1)},\]

\[G_S := G[V_S] - ((M_S \cup P^\phi) - ((S \cup L_S) \cup (\phi(S) \cup L_S))) - O_S.\]

Observe that (TR4*), and (TR4') imply that

\[|V(M_S \cup P_S)| \leq |V(T_{i+1}^r \cup R_{i+1}^r \cup \phi(R_{i+1}^r))| + \sum_{S' \in S'} |V(T_{S'} \cup R_{S'} \cup \phi(R_{S'}))| \leq 2 \gamma_{i+1}n + 2 \binom{h}{i} \gamma_{i+1}n \leq \gamma_i n.\]
In particular, $|V(P_S^\phi)| \leq |V(P_S) \cup V(H)| \leq \gamma_in + h$. Moreover, by Fact 5.4(i), (TR3*)i, and (TR3'), we have that $\Delta(O_S) \leq (2\kappa_{i+1} + 2^h\kappa')(f - r)$. Thus, by Proposition 5.9(v) $G_S$ is still a $(2\varepsilon, \xi/2, f, r)$-supercomplex. Moreover, note that $L_S \subseteq G_S(S)^{(r-1)} \cap G_S(\phi(S))^{(r-1)}$ and $|V(L_S)| \leq 1.1\gamma_{i+1}|V_S|$ by Claim 2 and that $L_S$ is $F(S^*)$-divisible by Claim 3.

Finally, by definition of $S_i$, $S$ is contained in some $e \in R_i$. Since $R_i$ satisfies (Y2) by (TR1*)i, we know that $\phi|_e$ is injective. Thus, $\phi|_S: S \rightarrow \phi(S)$ is a bijection. We can thus apply Lemma 8.10 with the following objects/parameters:

| object/parameter | $G$ | $r$ | $S$ | $\phi(S)$ | $|\phi|_S$ | $L_S$ | $1.1\gamma_{i+1}$ | $\gamma_{i+1}$ | $2\xi$ | $|V_S|$ | $\xi/2$ | $f$ | $r$ | $F$ | $F^*$ | $\kappa/2$ |
|------------------|-----|-----|-----|-----------|---------|-------|-----------------|------------|-----|-------|--------|-----|-----|-----|-------|--------|
| playing the role of | $G$ | $r$ | $S_1$ | $S_2$ | $\phi$ | $L$ | $\gamma$ | $\gamma$ | $\varepsilon$ | $n$ | $\xi$ | $f$ | $r$ | $F$ | $F^*$ | $\kappa$ |

This yields $T_S, R_S \subseteq G_S^{(r)}$ and $\kappa/2$-well separated $F$-packings $F_{S,1}, F_{S,2}$ such that (TR2')–(TR4') hold, $V(R_S) \subseteq V(G_S) \setminus \phi(S)$ and $|e \cap S| \in [i - 1]$ for all $e \in R_S$. Note that the latter implies that $R_S$ is $(\phi, V(G), V(H), V(H'), i - 1)$-projectable as $V(H) \cap V(G_S) = S$ and $V(H') \cap V(G_S) = \phi(S)$, so (TR1') holds as well. Moreover, using (TR2')i and (TR2') it is easy to see that our construction ensures that

(a) $H, H', t_{i+1}, R^*_i, \phi(R^*_i), (T_S)_{S \in S_i}, (R_S)_{S \in S_i}, (\phi(R_S))_{S \in S_i}$ are pairwise edge-disjoint;

(b) for all distinct $S, S' \in S_i$ and all $e \in R_S, e' \in R_{S'}, e'' \in R^*_{i+1} - R_i$ we have that $\phi(e), \phi(e')$ and $\phi(e'')$ are pairwise distinct;

(c) for any $j, j' \in [2]$ and all distinct $S, S' \in S_i, F_{S,j}$ is $(r + 1)$-disjoint from $F^*_{i+1,j'}$ and from $F_{S',j'}$.

Indeed, (a) holds by the choice of $M_S$, (b) holds by definition of $P_S^\phi$, and (c) holds by definition of $O_S$. Let

$$T^*_i := T^*_{i+1} \cup R_i \cup \phi(R_i) \cup \bigcup_{S \in S_i} T_S;$$

$$R^*_i := (R^*_{i+1} - R_i) \cup \bigcup_{S \in S_i} R_S;$$

$$F^*_{i,1} := F^*_{i+1,1} \cup \bigcup_{S \in S_i} F_{S,2};$$

$$F^*_{i,2} := F^*_{i+1,2} \cup \bigcup_{S \in S_i} F_{S,1}.$$  

Using (TR3*)i, (TR3'), (a) and (8.12), it is easy to check that both $F^*_{i,1}$ and $F^*_{i,2}$ are $F$-packings in $G$. We check that (TR1*)$i-1$–(TR4*)$i-1$ hold. Using (TR4*)i and (TR4'), we can confirm that

$$|V(T^*_i \cup R^*_i)| \leq |V(T^*_{i+1} \cup R^*_{i+1} \cup \phi(R^*_{i+1}))| + \sum_{S \in S_i} |V(T_S \cup R_S)|$$

$$\leq 2\gamma_{i+1}n + \binom{h}{i}\gamma_{i+1}n \leq \gamma_in,$$

so (TR4*)$i-1$ holds.

In order to check (TR1*)$i-1$, i.e. that $R^*_i$ is $(\phi, V(G), V(H), V(H'), i - 1)$-projectable, note that (Y1) and (Y2) hold by (TR1*)i, the definition of $R_i$ and (TR1'). Moreover, (Y3) is implied by (TR1*)i, (TR1') and (b).
Moreover, \((TR^2)_{i-1}\) follows from (a). Finally, we check \((TR^3)_{i-1}\). Observe that

\[
T_i^* \cup H \cup R_i^1 = T_{i+1}^* \cup R_i \cup \phi(R_i) \cup \bigcup_{S \in S_i} T_S \cup H \cup (R_{i+1}^* - R_i) \cup \bigcup_{S \in S_i} R_S
\]

(8.12)

\[
T_i^* \cup H^i \cup \phi(R_i^*) = T_{i+1}^* \cup R_i \cup \phi(R_i) \cup \bigcup_{S \in S_i} T_S \cup H^i \cup \phi(R_{i+1}^*) - \phi(R_i) \cup \bigcup_{S \in S_i} \phi(R_S)
\]

Thus, by \((TR3)^i\) and \((TR3)\), \(F_{i+1}^i\) is an \(F\)-decomposition of \(T_i^* \cup H \cup R_i^1\) and \(F_{i+2}^i\) is an \(F\)-decomposition of \(T_i^* \cup H^i \cup \phi(R_i^*)\). Moreover, by (c) and Fact 5.4(ii), \(F_{i+1}^i\) and \(F_{i+2}^i\) are both \((\kappa_i + 1 + (\frac{1}{2})\kappa')\)-well separated in \(G\). Since \(\kappa_i + 1 + (\frac{1}{2})\kappa' = \kappa_i\), this establishes \((TR3)^{i-1}\).

Finally, let \(T_i^*\), \(R_i\), \(F_{1,1}^i\), \(F_{1,2}^i\) satisfy \((TR^1)_{0}\)–\((TR^4)_{0}\). Note that \(R_i^1\) is empty by \((TR^1)_{0}\) and \((Y1)\). Moreover, \(T_i^* \subseteq (G)^{r}\) is edge-disjoint from \(H\) and \(H^r\) by \((TR^2)_{0}\) and \(\Delta(T_i^*) \leq \gamma_{1}N\) by \((TR^4)_{0}\). Most importantly, \(F_{1,1}^i\) and \(F_{1,2}^i\) are \(\kappa_i\)-well separated \(F\)-packings in \(G\) with \(F_{1,1}^{r} = T_i^* \cup H\) and \(F_{1,2}^{r} = T_i^* \cup H^i\) by \((TR^3)_{0}\). Therefore, \(T_i^*\) is a \(\kappa_i\)-well separated \((H, (H^i): F)\)-transformer in \(G\) with \(\Delta(T_i^*) \leq \gamma_{1}N\). Recall that \(\gamma_1 = \gamma\) and note that \(\kappa_1 \leq 2^h \kappa' \leq \kappa\). Thus, \(T_i^*\) is the desired transformer.

\[\square\]

8.2. Canonical multi-\(r\)-graphs. Roughly speaking, the aim of this section is to show that any \(F\)-divisible \(r\)-graph \(H\) can be transformed into a canonical multigraph \(M_h\) which does not depend on the structure of \(H\). However, it turns out that for this we need to move to a ‘dual’ setting, where we consider \(\nabla H\) which is obtained from \(H\) by applying an \(F\)-extension operator \(\nabla\). This operator allows us to switch between multi-\(r\)-graphs (which arise naturally in the construction but are not present in the complex \(G\) we are decomposing) and (simple) \(r\)-graphs (see e.g. Fact 8.18).

Given a multi-\(r\)-graph \(H\) and a set \(X\) of size \(r\), we say that \(\psi\) is an \(X\)-orientation of \(H\) if \(\psi\) is a collection of bijective maps \(\psi_e : X \rightarrow e\), one for each \(e \in H\). (For \(r = 2\) and \(X = \{1, 2\}\), say, this coincides with the notion of an oriented multigraph, e.g. by viewing \(\psi_e(1)\) as the tail and \(\psi_e(2)\) as the head of \(e\), where parallel edges can be oriented in opposite directions.)

Given an \(r\)-graph \(F\) and a distinguished edge \(e_0 \in F\), we introduce the following ‘extension’ operators \(\nabla_{(F, e_0)}\) and \(\nabla_{(F, e_0)}\).

**Definition 8.13** (Extension operators \(\nabla\) and \(\nabla\)). Given a (multi-)\(r\)-graph \(H\) with an \(e_0\)-orientation \(\psi\), let \(\nabla_{(F, e_0)}(H, \psi)\) be obtained from \(H\) by extending every edge of \(H\) into a copy of \(F\), with \(e_0\) being the rooted edge. More precisely, let \(Z_{e}\) be vertex sets of size \(|V(F) \setminus e_0|\) such that \(Z_{e} \cap Z_{e'} = \emptyset\) for all distinct (but possibly parallel) \(e, e' \in H\) and \(V(H) \cap Z_{e} = \emptyset\) for all \(e \in H\). For each \(e \in H\), let \(F_{e}\) be a copy of \(F\) on vertex set \(e \cup Z_{e}\) such that \(\psi_{e}(v)\) plays the role of \(v\) for all \(v \in e_0\) and \(Z_{e}\) plays the role of \(V(F) \setminus e_0\). Then \(\nabla_{(F, e_0)}(H, \psi) := \bigcup_{e \in H} F_{e}\). Let

\[
\nabla_{(F, e_0)}(H, \psi) := \nabla_{(F, e_0)}(H, \psi) - H
\]

Note that \(\nabla_{(F, e_0)}(H, \psi)\) is a (simple) \(r\)-graph even if \(H\) is a multi-\(r\)-graph. If \(F, e_0\) and \(\psi\) are clear from the context, or if we only want to motivate an argument before giving the formal proof, we just write \(\nabla H\) and \(\nabla H\).

**Fact 8.14.** Let \(F\) be an \(r\)-graph and \(e_0 \in F\). Let \(H\) be a multi-\(r\)-graph and let \(\psi\) be any \(e_0\)-orientation of \(H\). Then the following hold:

(i) \(\nabla_{(F, e_0)}(H, \psi)\) is \(F\)-decomposable;
(ii) \(\nabla_{(F, e_0)}(H, \psi)\) is \(F\)-divisible if and only if \(H\) is \(F\)-divisible.

The goal of this subsection is to show that for every \(h \in \mathbb{N}\), there is a multi-\(r\)-graph \(M_h\) such that for any \(F\)-divisible \(r\)-graph \(H\) on at most \(h\) vertices, we have

\[
\nabla(\nabla(H + t \cdot F) + s \cdot F) \sim \nabla M_h
\]
for suitable $s,t \in \mathbb{N}$. The multigraph $M_h$ is canonical in the sense that it does not depend on $H$, but only on $h$. The benefit is, very roughly speaking, that it allows us to transform any given leftover r-graph $H$ into the empty r-graph, which is trivially decomposable, and this will enable us to construct an absorber for $H$. Indeed, to see that (8.13) allows us to transform $H$ into the empty r-graph, let

$$H' := \nabla(\nabla(H + t \cdot F) + s \cdot F) = \nabla\nabla H + t \cdot \nabla\nabla F + s \cdot \nabla F.$$ 

Observe that the r-graph $T := \nabla H + t \cdot \nabla F + s \cdot F$ 'between' $H$ and $H'$ can be chosen in such a way that

$$T \cup H = \nabla H + t \cdot \nabla F + s \cdot F,$$

$$T \cup H' = \nabla(\nabla H + t \cdot (\nabla F) \cup F) + s \cdot \nabla F.$$ 

Thus, $T$ is an $(H,H';F)$-transformer (cf. Fact 8.14(i)). Hence, together with (8.13) and Lemma 8.5, this means that we can transform $H$ into $\nabla M_h$. Since $M_h$ does not depend on $H$, we can also transform the empty r-graph into $\nabla M_h$, and by transitivity we can transform $H$ into the empty graph, which amounts to an absorber for $H$ (the detailed proof of this can be found in Section 8.3).

We now give the rigorous statement of (8.13), which is the main lemma of this subsection.

**Lemma 8.15.** Let $r \geq 2$ and assume that $(*)_i$ is true for all $i \in [r-1]$. Let $F$ be a weakly regular r-graph and $e_0 \in F$. Then for all $h \in \mathbb{N}$, there exists a multi-r-graph $M_h$ such that for any $F$-divisible r-graph $H$ on at most $h$ vertices, we have

$$\nabla(F,e_0)(\nabla(F,e_0)(H + t \cdot F, \psi_1) + s \cdot F, \psi_3) \rightarrow \nabla(F,e_0)(M_h, \psi_2)$$

for suitable $s,t \in \mathbb{N}$, where $\psi_1$ and $\psi_2$ can be arbitrary $e_0$-orientations of $H + t \cdot F$ and $M_h$, respectively, and $\psi_3$ is an $e_0$-orientation depending on these.

The above graphs $\nabla(\nabla(H + t \cdot F) + s \cdot F)$ and $\nabla M_h$ will be part of our $F$-absorber for $H$. We therefore need to make sure that we can actually find them in a supercomplex $G$. This requirement is formalised by the following definition.

**Definition 8.16.** Let $G$ be a complex, $X \subseteq V(G)$, $F$ an r-graph with $f := |V(F)|$ and $e_0 \in F$. Suppose that $H \subseteq G^{(r)}$ and that $\psi$ is an $e_0$-orientation of $H$. By extending $H$ with a copy of $\nabla(F,e_0)(H, \psi)$ in $G$ (whilst avoiding $X$) we mean the following: for each $e \in H$, let $Z_e \in G^{(f)}(e)$ be such that $Z_e \cap (V(H) \cup X) = \emptyset$ for every $e \in H$ and $Z_e \cap Z_{e'} = \emptyset$ for all distinct $e,e' \in H$. For each $e \in H$, let $F_e$ be a copy of $F$ on vertex set $e \cup Z_e$ (so $F_e \subseteq G^{(r)}$) such that $\psi_e(v)$ plays the role of $v$ for all $v \in e_0$ and $Z_e$ plays the role of $V(F) \setminus e_0$. Let $H^{\nabla} := \bigcup_{e \in H} F_e - H$ and $F := \{F_e : e \in H\}$ be the output of this.

For our purposes, the set $|V(H) \cup X|$ will have a small bounded size compared to $|V(G)|$. Thus, if the $G^{(f)}(e)$ are large enough (which is the case e.g. in an $(\varepsilon, \xi, f, r)$-supercomplex), then the above extension can be carried out simply by picking the sets $Z_e$ one by one.

**Fact 8.17.** Let $(H^{\nabla}, F)$ be obtained by extending $H \subseteq G^{(r)}$ with a copy of $\nabla(F,e_0)(H, \psi)$ in $G$. Then $H^{\nabla} \subseteq G^{(r)}$ is a copy of $\nabla(F,e_0)(H, \psi)$ and $F$ is a 1-well separated F-packing in $G$ with $F^{(r)} = H \cup H^{\nabla}$ such that for all $F' \subseteq F$, $|V(F') \cap V(H)| \leq r$.

For a partition $\mathcal{P} = \{V_x\}_{x \in X}$ whose classes are indexed by a set $X$, we define $V_Y := \bigcup_{x \in Y} V_x$ for every subset $Y \subseteq X$. Recall that for a multi-r-graph $H$ and $e \in (\nabla r)(H)$, $|H(e)|$ denotes the multiplicity of $e$ in $H$. For multi-r-graphs $H, H'$, we write $H \overset{\mathcal{P}}{\sim} H'$ if $\mathcal{P} = \{V_x\}_{x' \in V(H')}$ is a partition of $V(H')$ such that

(1) for all $x' \in V(H')$ and $e \in H$, $|V_{x'} \cap e| \leq 1$;

(2) for all $e' \in (\nabla r)(H')$, $\sum_{e \in e'} |H(e)| = |H'(e')|$. 

Given $\mathcal{P}$, define $\varphi_\mathcal{P}: V(H) \rightarrow V(H')$ as $\varphi_\mathcal{P}(x) := x'$ where $x'$ is the unique $x' \in V(H')$ such that $x \in V_{x'}$. Note that by (1), we have $|\{\varphi_\mathcal{P}(x) : x \in e\}| = r$ for all $e \in H$. Further, by (2), there exists a bijection $\Phi_\mathcal{P}: H \rightarrow H'$ between the multi-edge-sets of $H$ and $H'$ such that for every edge
that $e \in H$, the image $\Phi_P(e)$ is an edge consisting of the vertices $\phi_P(x)$ for all $x \in e$. It is easy to see that $H \cong H'$ if and only if there is some $P$ such that $H \overset{P}{\cong} H'$.

The extension operator $\nabla$ is well behaved with respect to the identification relation $\cong$ in the following sense: if $H \cong H'$, then $\nabla H \cong \nabla H'$. More precisely, let $H$ and $H'$ be multi-$r$-graphs and suppose that $H \overset{P}{\cong} H'$. Let $\phi_P$ and $\Phi_P$ be defined as above. Let $F$ be an $r$-graph and $e_0 \in F$. For any $e_0$-orientation $\psi'$ of $H'$, we define an $e_0$-orientation $\psi$ of $H$ induced by $\psi'$ as follows: for every $e \in H$, let $e' := \Phi_P(e)$ be the image of $e$ with respect to $\cong$. We have that $\phi_P|_e : e \to e'$ is a bijection. We now define the bijection $\psi : e_0 \to e$ as $\psi_e := \phi_P|_e^{-1} \circ \psi_e'$, where $\psi'_e : e_0 \to e'$. Thus, the collection $\psi$ of all $\psi_e$, $e \in H$, is an $e_0$-orientation of $H$. It is easy to see that $\psi$ satisfies the following.

**Fact 8.18.** Let $F$ be an $r$-graph and $e_0 \in F$. Let $H, H'$ be multi-$r$-graphs and suppose that $H \cong H'$. Then for any $e_0$-orientation $\psi'$ of $H'$, we have $\nabla_{(F,e_0)}(H, \psi) \cong \nabla_{(F,e_0)}(H', \psi')$, where $\psi$ is induced by $\psi'$.

We now define the multi-$r$-graphs which will serve as the canonical multi-$r$-graphs $M_k$ in (8.13). For $r \in \mathbb{N}$, let $\mathcal{M}_r$ contain all pairs $(k, m) \in \mathbb{N}^2$ such that $\frac{m}{r-1}(\frac{k-1}{r-1})$ is an integer for all $i \in [r - 1]_0$.

**Definition 8.19 (Canonical multi-$r$-graph).** Let $F^*$ be an $r$-graph and $e^* \in F^*$. Let $V' := V(F^*) \setminus e^*$. If $(k, m) \in \mathcal{M}_r$, define the multi-$r$-graph $M_{k,m}^{(F^*, e^*)}$ on vertex set $[k] \cup V'$ such that for every $e \in (\binom{[k] \cup V'}{r})$, the multiplicity of $e$ is

\[
|M_{k,m}^{(F^*, e^*)}(e)| = \begin{cases} 
0 & \text{if } e \subseteq [k]; \\
\frac{m}{r-1}(\frac{k-|e\cap[k]|}{r-1-|e\cap[k]|}) & \text{if } |e \cap [k]| > 0, |e \cap V'| > 0; \\
0 & \text{if } e \subseteq V', e \notin F^*; \\
\frac{m}{r-1}(\frac{k}{r-1}) & \text{if } e \subseteq V', e \in F^*. 
\end{cases}
\]

We will require the graph $F^*$ in Definition 8.19 to have a certain symmetry property with respect to $e^*$, which we now define. We will prove the existence of a suitable ($F$-decomposable) symmetric r-extender in Lemma 8.26.

**Definition 8.20 (symmetric r-extender).** We say that $(F^*, e^*)$ is a symmetric r-extender if $F^*$ is an $r$-graph, $e^* \in F^*$ and the following holds:

(SE) for all $e' \in (\binom{V(F^*)}{r})$ with $e' \cap e^* \neq \emptyset$, we have $e' \in F^*$.

Note that if $(F^*, e^*)$ is a symmetric r-extender, then the operators $\nabla_{(F^*, e^*)}, \nabla_{(F^*, e^*)}$ are labelling-invariant, i.e. $\nabla_{(F^*, e^*)}(H, \psi_1) \cong \nabla_{(F^*, e^*)}(H, \psi_2)$ and $\nabla_{(F^*, e^*)}(H, \psi_1) \cong \nabla_{(F^*, e^*)}(H, \psi_2)$ for all $e^*$-orientations $\psi_1, \psi_2$ of a multi-$r$-graph $H$. We therefore simply write $\nabla_{(F^*, e^*)}H$ and $\nabla_{(F^*, e^*)}H$ in this case.

To prove Lemma 8.15 we introduce so called strong colourings. Let $H$ be an $r$-graph and $C$ a set. A map $c : V(H) \to C$ is a strong $C$-colouring of $H$ if for all distinct $x, y \in V(H)$ with $|H([x, y])| > 0$, we have $c(x) \neq c(y)$, that is, no colour appears twice in one edge. For $\alpha \in C$, let $c^{-1}(\alpha)$ denote the set of all vertices coloured $\alpha$. For a set $C' \subseteq C$, we define $c^{C'}(C) := \{e \in H : C' \subseteq c(e)\}$. We say that $c$ is $m$-regular if $|c^{C'}(C)| = m$ for all $C' \in \binom{C}{r-1}$. For example, an $r$-partite $r$-graph $H$ trivially has a strong $|H|$-regular $[r]$-colouring.

**Fact 8.21.** Let $H$ be an $r$-graph and let $c$ be a strong $m$-regular $[k]$-colouring of $H$. Then $c^{C'}(C) = \frac{m}{r-1}(\frac{k-1}{r-1})$ for all $i \in [r - 1]_0$ and all $C' \in \binom{C}{r-1}$.

**Lemma 8.22.** Let $(F^*, e^*)$ be a symmetric r-extender. Suppose that $H$ is an $r$-graph and suppose that $c$ is a strong $m$-regular $[k]$-colouring of $H$. Then $(k, m) \in \mathcal{M}_r$ and

$$\nabla_{(F^*, e^*)}H \cong M_{k,m}^{(F^*, e^*)}.$$
Proof. By Fact 8.21, \((k, m) \in \mathcal{M}_r\), thus \(M_{k,m}^{(F^*, e^*)}\) is defined. Recall that \(M_{k,m}^{(F^*, e^*)}\) has vertex set \([k] \cup V'\), where \(V' := V(F^*) \setminus e^*\). Let \(V(H) \cup \bigcup_{e \in H} Z_e\) be the vertex set of \(\nabla_{(F^*, e^*)} H\) as in Definition 8.13, with \(Z_e = \{ze,v : v \in V'\}\). We define a partition \(\mathcal{P}\) of \(V(H) \cup \bigcup_{e \in H} Z_e\) as follows: for all \(i \in [k]\), let \(V_i := c^{-1}(i)\). For all \(v \in V'\), let \(V_v := \{ze,v : e \in H\}\). We now claim that \(\nabla_{(F^*, e^*)} H \cong M_{k,m}^{(F^*, e^*)}\).

Clearly, \(\mathcal{P}\) satisfies (I1) because \(c\) is a strong colouring of \(H\). For a set \(e' \in (\binom{[k]}{r})\), define

\[
S_{e'} := \{e'' \in \nabla_{(F^*, e^*)} H : e'' \subseteq V_e'\}.
\]

Since \(\nabla_{(F^*, e^*)} H\) is simple, in order to check (I2), it is enough to show that for all \(e' \in (\binom{[k]}{r})\), we have \(|S_{e'}| = |M_{k,m}^{(F^*, e^*)}(e')|\). We distinguish three cases.

Case 1: \(e' \subseteq [k]\)

In this case, \(|M_{k,m}^{(F^*, e^*)}(e')| = 0\). Since \(V_{e'} \subseteq V(H)\) and \((\nabla_{(F^*, e^*)} H)[V(H)]\) is empty, we have \(S_{e'} = \emptyset\), as desired.

Case 2: \(e' \not\subseteq [k]\)

In this case, \(S_{e'}\) consists of all edges of \(\nabla_{(F^*, e^*)} H\) which play the role of \(e'\) in \(F^*_r\) for some \(e \in H\). Hence, if \(e' \not\in F^*_r\), then \(|S_{e'}| = 0\), and if \(e' \in F^*_r\), then \(|S_{e'}| = |H|\). Fact 8.21 applied with \(i = 0\) yields \(|H| = \frac{k!}{r! (k-r)!}\), as desired.

Case 3: \(|e' \cap [k]| > 0\) and \(|e' \cap V'| > 0\)

We claim that \(|S_{e'}| = |c^c(e' \cap [k])|\). In order to see this, we define a bijection \(\pi: c^c(e' \cap [k]) \to S_{e'}\) as follows: for every \(e \in H\) with \(e' \cap [k] \subseteq c(e)\), define

\[
\pi(e) := (e \cap c^{-1}(e' \cap [k])) \cup \{ze,v : v \in e' \cap V'\}.
\]

We first show that \(\pi(e) \in S_{e'}\). Note that \(e \cap c^{-1}(e' \cap [k])\) is a subset of \(e\) of size \(|e' \cap [k]|\) and \(\{ze,v : v \in e' \cap V'\}\) is a subset of \(Z_e\) of size \(|e' \cap V'|\). Hence, \(\pi(e) \in (V(F^*_r))\) and \(|\pi(e) \cap e'| = |e' \cap [k]| > 0\). Thus, by (SE), we have \(\pi(e) \in F^*_r \subseteq \nabla_{(F^*, e^*)} H\). (This is in fact the crucial point where we need (SE).) Moreover,

\[
\pi(e) \subseteq c^{-1}(e' \cap [k]) \cup \{ze,v : v \in e' \cap V'\} \subseteq V_{e' \cap [k]} \cup V_{e' \cap V'} = V_{e'}.
\]

Therefore, \(\pi(e) \in S_{e'}\). It is straightforward to see that \(\pi\) is injective. Finally, for every \(e'' \in S_{e'}\), we have \(e'' = \pi(e)\), where \(e \in H\) is the unique edge of \(H\) with \(e'' \in F^*_r\). This establishes our claim that \(\pi\) is bijective and hence \(|S_{e'}| = |c^c(e' \cap [k])|\). Since \(1 \leq |e' \cap [k]| \leq r - 1\), Fact 8.21 implies that

\[
|S_{e'}| = |c^c(e' \cap [k])| = \frac{m}{r} = \frac{k - |e' \cap [k]|}{r - 1 - |e' \cap [k]|} = |M_{k,m}^{(F^*, e^*)}(e')|,
\]

as required. \(\square\)

Next, we establish the existence of suitable strong regular colourings. As a tool we need the following result about decompositions of very dense multi-\(r\)-graphs (which we will apply with \(r - 1\) playing the role of \(r\)).

Lemma 8.23. Let \(r \in \mathbb{N}\) and assume that \((*)_r\) is true. Let \(1/n < 1/h, 1/f\) with \(f > r\), let \(F\) be a weakly regular \(r\)-graph on \(f\) vertices and assume that \(K_n^{(r)}\) is \(F\)-divisible. Let \(m \in \mathbb{N}\). Suppose that \(H\) is an \(F\)-divisible multi-\(r\)-graph on \([h]\) with multiplicity at most \(m - 1\) and let \(K\) be the complete multi-\(r\)-graph on \([n]\) with multiplicity \(m\). Then \(K - H\) has an \(F\)-decomposition.

Proof. Choose \(\varepsilon > 0\) such that \(1/n \ll \varepsilon \ll 1/h, 1/f\). Fix an edge \(e_0 \in F\). Let \(\psi\) be any \(e_0\)-orientation of \(H\). We may assume that \(\tilde{H} := \nabla_{(F,e_0)}(H, \psi)\) is a multi-\(r\)-graph on \([n]\). Let \(\hat{\psi}\) be any \(e_0\)-orientation of \(H^* := \tilde{H} - H\). We may also assume that \(\hat{H} := \nabla_{(F,e_0)}(H^*, \hat{\psi})\) is an \(r\)-graph on \([n]\). Let \(H^1 := \tilde{H} - H^*\). Using Fact 8.14, observe that the following are true:

(a) \(H\) can be decomposed into \(m - 1\) (possibly empty) \(F\)-decomposable (simple) \(r\)-graphs \(H'_1, \ldots, H'_{m-1}\);
(b) \( \hat{H} \) is an \( F \)-decomposable (simple) \( r \)-graph;
(c) \( H^\dagger \) is an \( F \)-divisible (simple) \( r \)-graph;
(d) \( H \cup \hat{H} = \hat{H} \cup H^\dagger \).

By (d), we have that
\[
K - H = (K - \hat{H} - \hat{H}) \cup \hat{H} = \hat{H} \cup (K - \hat{H} - H^\dagger).
\]

Let \( K' \) be the complete (simple) \( r \)-graph on \([n]\). For each \( i \in [m - 1] \), define \( H_i := K' - H_i^\dagger \), and let \( H_m := K' - H^\dagger \). We thus have \( K - \hat{H} - H^\dagger = \bigcup_{i \in [m]} H_i \) by (a).

Recall that \( K'^{r^*} \) is a \((0, 0.99/f!, f, r)\)-supercomplex (cf. Example 4.9). We conclude with Proposition 5.9(v) that \( H_i^{r^*} = K'^{r^*} - H_i^\dagger \) is an \((\varepsilon, 0.5/f!, f, r)\)-supercomplex for every \( i \in [m] \).

Recall that \( K' \) is \( F \)-divisible by assumption. Thus, by (a) and (c), each \( H_i \) is \( F \)-divisible. Hence, by (a), \( H_i \) is \( F \)-decomposable for every \( i \in [m] \). Thus,
\[
K - H = \hat{H} \cup (K - \hat{H} - H^\dagger) = \hat{H} \cup \bigcup_{i \in [m]} H_i
\]

has an \( F \)-decomposition by (b).

The next lemma guarantees the existence of a suitable strong regular colouring. For this, we apply Lemma 8.23 to the shadow of \( F \). For an \( r \)-graph \( F \), define the shadow \( F^{sh} \) of \( F \) to be the \((r - 1)\)-graph on \( V(F) \) where an \((r - 1)\)-set \( S \) is an edge if and only if \( |F(S)| > 0 \). We need the following fact.

\textbf{Fact 8.24. If } \( F \) is a weakly \((s_0, \ldots, s_{r-1})\)-regular \( r \)-graph, then \( F^{sh} \) is a weakly \((s'_0, \ldots, s'_{r-2})\)-regular \((r - 1)\)-graph, where \( s'_i := \frac{r - i}{s_i - 1} s_i \) for all \( i \in [r - 2] \).

\textbf{Proof.} Let \( i \in [r - 2] \). For every \( T \in \binom{V(F)}{i} \), we have \( |F^{sh}(T)| = \frac{r - i}{s_i - 1} |F(T)| \) since every edge of \( F \) which contains \( T \) contains \( r - i \) edges of \( F^{sh} \) which contain \( T \), but each such edge of \( F^{sh} \) is contained in \( s_i - 1 \) such edges of \( F \). This implies the fact.

\textbf{Lemma 8.25. Let } \( r \geq 2 \) and assume that \((*)_{r-1}\) holds. Let \( F \) be a weakly regular \( r \)-graph. Then for all \( h \in \mathbb{N} \), there exist \( k, m \in \mathbb{N} \) such that for any \( F \)-divisible \( r \)-graph \( H \) on at most \( h \) vertices, there exists \( t \in \mathbb{N} \) such that \( H + t \cdot F \) has a strong \( m \)-regular \([k]\)-colouring.

\textbf{Proof.} Let \( f := |V(F)| \) and suppose that \( F \) is weakly \((s_0, \ldots, s_{r-1})\)-regular. Thus, for every \( S \in \binom{V(F)}{r-1} \), we have
\[
|F(S)| = \begin{cases} 
\frac{s_{r-1}}{s_{r-1} - 1} & \text{if } S \in F^{sh}; \\
0 & \text{otherwise}.
\end{cases}
\]

By Proposition 5.2, we can choose \( k \in \mathbb{N} \) such that \( 1/k \ll 1/h, 1/f \) and such that \( K_k^{(r-1)} \) is \( F^{sh} \)-divisible. Let \( G \) be the complete multi-\((r - 1)\)-graph on \([k]\) with multiplicity \( m' := h + 1 \) and let \( m := s_{r-1} m' \).

Let \( H \) be any \( F \)-divisible \( r \)-graph on at most \( h \) vertices. By adding isolated vertices to \( H \) if necessary, we may assume that \( V(H) = [h] \). We first define a multi-\((r - 1)\)-graph \( H' \) on \([h]\) as follows: For each \( S \in \binom{[h]}{r-1} \), let the multiplicity of \( S \) in \( H' \) be \( |H'(S)| := |H(S)| \). Clearly, \( H' \) has multiplicity at most \( h \). Observe that for each \( S \subseteq [h] \) with \( |S| \leq r - 1 \), we have
\[
|H'(S)| = (r - |S|)(H(S)).
\]

Note that since \( H \) is \( F \)-divisible, we have that \( s_{r-1} | |H(S)| \) for all \( S \in \binom{[h]}{r-1} \). Thus, the multiplicity of each \( S \in \binom{[h]}{r-1} \) in \( H' \) is divisible by \( s_{r-1} \). Let \( H'' \) be the multi-\((r - 1)\)-graph on \([h]\) obtained from \( H' \) by dividing the multiplicity of each \( S \in \binom{[h]}{r-1} \) by \( s_{r-1} \). Hence, by (8.15), for all \( S \subseteq [h] \) with \( |S| \leq r - 1 \), we have
\[
|H''(S)| = \frac{|H'(S)|}{s_{r-1}} = \frac{r - |S|}{s_{r-1}} |H(S)|.
\]
For each $S \in \binom{[r]}{r-1}$ with $S \not\subseteq [h]$, we set $|H''(S)| := |H(S)| := 0$. Then (8.16) still holds.

We claim that $H''$ is $F^{sh}$-divisible. Recall that by Fact 8.24,

$$F^{sh}$$

is weakly $(\frac{r-i}{s_{r-1}} s_0, \ldots, \frac{r-i}{s_{r-1}} s_i, \ldots, \frac{2}{s_{r-1}} s_{r-2})$-regular.

Let $i \in [r-2]_0$ and let $S \in \binom{[h]}{i}$. We need to show that $|H''(S)| \equiv 0 \mod \deg(F^{sh})$, where $\deg(F^{sh}) = \frac{r-i}{s_{r-1}} s_i$. Since $H$ is $F$-divisible, we have $|H(S)| \equiv 0 \mod s_i$. Together with (8.16), we deduce that $|H''(S)| \equiv 0 \mod \frac{r-i}{s_{r-1}} s_i$. Hence, $H''$ is $F^{sh}$-divisible. Therefore, by Lemma 8.23 (with $m, m', r - 1, F^{sh}$ playing the roles of $n, m, r, F$) and our choice of $k$, $G - H''$ has an $F^{sh}$-decomposition $F''$ into $t$ edge-disjoint copies $F_1', \ldots, F_t'$ of $F^{sh}$.

We will show that $t$ is as required in Lemma 8.25. To do this, let $F_1, \ldots, F_t$ be vertex-disjoint copies of $F$ which are also vertex-disjoint from $H$. We will now define a strong $m$-regular $[k]$-colouring $c$ of $H^{\perp} := H \cup \bigcup_{j \in [t]} F_j$.

Let $c_0$ be the identity map on $V(H) = [h]$, and for each $j \in [t]$, let

$$c_j : V(F_j) \to V(F_j')$$

(recall that $V(F_j') = V(F_j)$). Since $H, F_1, \ldots, F_t$ are vertex-disjoint and $V(H) \cup \bigcup_{j \in [t]} V(F_j') \subseteq [k]$, we can combine $c_0, c_1, \ldots, c_t$ to a map

$$c : V(H^{\perp}) \to [k],$$

i.e. for $x \in V(H^{\perp})$, we let $c(x) := c_j(x)$, where either $j$ is the unique index for which $x \in V(F_j)$ or $j = 0$ if $x \in V(H)$. For every edge $e \in H^{\perp}$, we have $e \subseteq V(H)$ or $e \subseteq V(F_j)$ for some $j \in [t]$, thus $c|_e$ is injective. Therefore, $c$ is a strong $[k]$-colouring of $H^{\perp}$.

It remains to check that $c$ is $m$-regular. Let $C \in \binom{[r]}{r-1}$. Clearly, $|c^C(C)| = \sum_{j=0}^t |c^C_j(C)|$. Since every $c_j$ is a bijection, we have

$$|c^C_0(C)| = |\{ e \in H : c_0^{-1}(C) \subseteq e \}| = |H(c_0^{-1}(C))| = |H(C)|$$

and

$$|c^C_j(C)| = |F_j(c_j^{-1}(C))| \overset{(8.14)}{=} \begin{cases} s_{r-1} & \text{if } c_j^{-1}(C) \in F_j^{sh} \overset{(8.17)}{\iff} C \in F_j' \\ 0 & \text{otherwise.} \end{cases}$$

Thus, we have $|c^C(C)| = |H(C)| + s_{r-1}|J(C)|$, where

$$J(C) := \{ j \in [t] : C \in F_j' \}.$$ 

Now crucially, since $F''$ is an $F^{sh}$-decomposition of $G - H''$, we have that $|J(C)|$ is equal to the multiplicity of $C$ in $G - H''$, i.e. $|J(C)| = m' - |H''(C)|$. Thus,

$$|c^C(C)| = |H(C)| + s_{r-1}|J(C)| \overset{(8.16)}{=} s_{r-1}(|H''(C)| + |J(C)|) = s_{r-1}m' = m,$$

completing the proof.

Before we can prove Lemma 8.15, we need to show the existence of a symmetric $r$-extender $F^*$ which is $F$-decomposable. For some $F$ we could actually take $F^* = F$ (e.g. if $F$ is a clique). For general (weakly regular) $r$-graphs $F$, we will use the Cover down lemma (Lemma 7.7) to find $F^*$. At first sight, appealing to the Cover down lemma may seem rather heavy handed, but a direct construction seems to be quite difficult.

**Lemma 8.26.** Let $F$ be a weakly regular $r$-graph, $e_0 \in F$ and assume that $(\ast)_i$ is true for all $i \in [r-1]$. There exists a symmetric $r$-extender $(F^*, e^*)$ such that $F^*$ has an $F$-decomposition $\mathcal{F}$ with $e^* \in F^* \in \mathcal{F}$ and $e^*$ plays the role of $e_0$ in $F^*$. 

**Proof.** Let $f := |V(F)|$. By Proposition 5.2, we can choose $n \in \mathbb{N}$ and $\gamma, \varepsilon, \nu, \mu > 0$ such that $1/n \ll \gamma \ll \varepsilon \ll \nu \ll \mu \ll 1/f$ and such that $K_n^{(\nu)}$ is $F$-divisible. By Example 4.9, $K_n$ is a $(0,0.99/f!, f, r)$-supercomplex. By Fact 7.2(i) and Proposition 7.12, there exists $U \subseteq V(K_n)$ of size $\lceil \gamma n \rceil$ which is $(\varepsilon, \mu, 0.9/f!, f, r)$-random in $K_n$. Let $U := V(K_n) \setminus U$. Using
(R2) of Definition 7.1, it is easy to see that \(K_n\) is \((\varepsilon, f, r)\)-dense with respect to \(K_{n}^{(r)} - K_{n}^{(r)}[\bar{U}]\) (see Definition 7.6). Thus, by the Cover down lemma (Lemma 7.7), there exists a subgraph \(H^*\) of \(K_{n}^{(r)} - K_{n}^{(r)}[\bar{U}]\) with \(\Delta(H^*) \leq \gamma n\) and the following property: for all \(L \subseteq K_{n}^{(r)}\) such that \(\Delta(L) \leq \gamma n\) and \(H^* \cup L\) is \(F\)-divisible, \(H^* \cup L\) has an \(F\)-packing which covers all edges except possibly some inside \(U\).

Let \(F'\) be a copy of \(F\) with \(V(F') \subseteq \bar{U}\). Let \(G_{\text{nibble}} := K_n - H^* - F'\). By Proposition 5.9(v), \(G_{\text{nibble}}\) is a \((2^{2r+2}\nu, 0.8/f!\), \(f, \nu)\)-supercomplex. Thus, by Lemma 6.5, there exists an \(F\)-packing \(F_{\text{nibble}}\) in \(G_{\text{nibble}}^{(r)}\) such that \(\Delta(L) \leq \gamma n\), where \(L := e_{\text{nibble}} - F_{\text{nibble}}^{(r)}\). Clearly, \(H^* \cup L = K_{n}^{(r)} - F_{\text{nibble}}^{(r)} - F'\) is \(F\)-divisible. Thus, there exists an \(F\)-packing \(F^*\) in \(H^* \cup L\) which covers all edges of \(H^* \cup L\) except possibly some inside \(U\). Let \(F := \{F'\} \cup F_{\text{nibble}} \cup F^*\). Let \(F^* := F^{(r)}\) and let \(e^*\) be the edge in \(F'\) which plays the role of \(e_0\).

Clearly, \(F\) is an \(F\)-decomposition of \(F^*\) with \(e^* \in F' \in F\) and \(e^*\) plays the role of \(e_0\) in \(F'\). It remains to check (SE). Let \(\ell \in \{K_r\}^{(r)}\) with \(\ell' \cap e^* \neq \emptyset\). Since \(e^* \subseteq \bar{U}\), \(\ell'\) cannot be inside \(U\). Thus, \(\ell'\) is covered by \(F\) and we have \(\ell' \in F^*\).

Note that \(|V(F^*)|\) is quite large here, in particular \(1/|V(F^*)| < 1/f\) for \(f = |V(F)|\). This means that \(G\) being an \((\varepsilon, 0, \nu)\)-supercomplex does not necessarily allow us to extend a given subgraph \(H\) of \(G^{(r)}\) to a copy of \(\nabla(F^* \cdot e^*)\) as described in Definition 8.16. Fortunately, this will in fact not be necessary, as \(F^*\) will only serve as an abstract auxiliary graph and will not appear as a subgraph of the absorber. (This is crucial since otherwise we would not be able to prove our main theorems with explicit bounds, let alone the bounds given in Theorem 1.4.)

We are now ready to prove Lemma 8.15.

**Proof of Lemma 8.15.** Given \(F\) and \(e_0\), we first apply Lemma 8.26 to obtain a symmetric \(r\)-extender \((F^*, e^*)\) such that \(F^*\) has an \(F\)-decomposition \(F\) with \(e^* \in F' \in F\) and \(e^*\) plays the role of \(e_0\) in \(F'\). For given \(h \in \mathbb{N}\), let \(k, m \in \mathbb{N}\) be as in Lemma 8.25. Clearly, we may assume that there exists an \(F\)-divisible \(r\)-graph on at most \(h\) vertices. Together with Lemma 8.22, this implies that \((k, m) \in \mathcal{M}_r\). Define

\[M_h := M_{k,m}^{(r,e^*)}\]

Now, let \(H\) be any \(F\)-divisible \(r\)-graph on at most \(h\) vertices. By Lemma 8.25, there exists \(t \in \mathbb{N}\) such that \(H + t \cdot F\) has a strong \(m\)-regular \([k]\)-colouring. By Lemma 8.22, we have

\[\nabla(F^* \cdot e^*)(H + t \cdot F) \Rightarrow M_h\]

Let \(\psi_1\) be any \(e_0\)-orientation of \(H + t \cdot F\). Observe that since \(e^*\) plays the role of \(e_0\) in \(F'\), \(\nabla(F^* \cdot e^*)(H + t \cdot F)\) can be decomposed into a copy of \(\nabla(F_0)(H + t \cdot F, \psi_1)\) and \(s\) copies of \(F\) (where \(s = |H + t \cdot F| \cdot |F|\setminus \{F'\}\)). Hence, we have

\[\nabla(F_0)(H + t \cdot F, \psi_1) + s \cdot F \Rightarrow \nabla(F^* \cdot e^*)(H + t \cdot F)\]

by Proposition 8.4(ii). Thus, \(\nabla(F_0)(H + t \cdot F, \psi_1) + s \cdot F \Rightarrow M_h\) by transitivity of \(\Rightarrow\). Finally, let \(\psi_2\) be any \(e_0\)-orientation of \(M_h\). By Fact 8.18, there exists an \(e_0\)-orientation \(\psi_3\) of \(\nabla(F_0)(H + t \cdot F, \psi_1) + s \cdot F\) such that

\[\nabla(F_0)(\nabla(F_0)(H + t \cdot F, \psi_1) + s \cdot F, \psi_3) \Rightarrow \nabla(F_0)(M_h, \psi_2)\]

\[\Box\]

**8.3. Proof of the Absorbing lemma.** As discussed at the beginning of Section 8.2, we can now combine Lemma 8.5 and Lemma 8.15 to construct the desired absorber by concatenating transformers between certain auxiliary \(r\)-graphs, in particular the extension \(\nabla M_h\) of the canonical multi-\(r\)-graph \(M_h\). It is relatively straightforward to find these auxiliary \(r\)-graphs within a given supercomplex \(G\). The step when we need to find \(\nabla M_h\) is the reason why the definition of a supercomplex includes the notion of extendability.

**Proof of Lemma 8.2.** If \(H\) is empty, then we can take \(A\) to be empty and it will be a \(\kappa\)-well separated \(F\)-absorber for \(H\) in \(G\) with \(\Delta(A) = 0\). So let us assume that \(H\) is not empty. In particular, \(G^{(r)}\) is not empty. Recall also that we assume \(r \geq 2\). Let \(e_0 \in F\) and
let $M_h$ be as in Lemma 8.15. Fix any $e_0$-orientation $\psi$ of $M_h$. By Lemma 8.15, there exist $t_1, t_2, s_1, s_2, \psi_1, \psi_2', \psi_2''$ such that

\begin{align}
\nabla_{(F,e_0)}(H + t_1 \cdot F, \psi_1) + s_1 \cdot F, \psi_2' &\sim \nabla_{(F,e_0)}(M_h, \psi); \\
\nabla_{(F,e_0)}(H(t_2 \cdot F, \psi_2') + s_2 \cdot F, \psi_2'') &\sim \nabla_{(F,e_0)}(M_h, \psi).
\end{align}

We can assume that $1/n \ll 1/\ell$ where $\ell := \max\{|V(M_h)|, t_1, t_2, s_1, s_2\}$.

Since $G$ is $(\xi, f + r, r)$-dense, there exist disjoint $Q_1, \ldots, Q_{t_1}, Q_{2,1}, \ldots, Q_{2,t_2} \in G(j)$ which are also disjoint from $V(H)$. For $j \in [t_1]$, let $F_{i,j}$ be a copy of $F$ with $V(F_{i,j}) = Q_{i,j}$. (For brevity, we omit mentioning that $i \in [2]$ throughout this proof when there is no danger of confusion.) Let $H_1 := H \cup \bigcup_{j \in [t_1]} F_{1,j}$ and $H_2 := \bigcup_{j \in [t_2]} F_{2,j}$ and (for $i \in [2]$) define

$$F_i := \{F_{i,j} : j \in [t_i]\}.$$ 

So $H_1$ is a copy of $H + t_1 \cdot F$ and $H_2$ is a copy of $t_2 \cdot F$. In fact, we will from now on assume (by redefining $\psi_1$ and $\psi_2'$) that we have

\begin{equation}
\nabla_{(F,e_0)}(H_1, \psi_1) + s_1 \cdot F, \psi_2' \sim \nabla_{(F,e_0)}(M_h, \psi).
\end{equation}

Let $(H_1', F_1')$ be obtained by extending $H_1$ with a copy of $\nabla_{(F,e_0)}(H_1, \psi_1)$ in $G$ (cf. Definition 8.16). We can assume that $H_1'$ and $H_2'$ are vertex-disjoint by first choosing $H_1'$ whilst avoiding $V(H_2)$ and subsequently choosing $H_2'$ whilst avoiding $V(H_1')$. (To see that this is possible we can e.g. use the fact that $G$ is $(\varepsilon, d, f, r)$-regular for some $d \geq \xi$.)

There exist disjoint $Q_{1,1}', \ldots, Q_{s_1}', Q_{2,1}', \ldots, Q_{2,s_2}' \in G(j)$ which are also disjoint from $V(H_1') \cup V(H_2')$. For $j \in [s_1]$, let $F_{1,j}'$ be a copy of $F$ with $V(F_{1,j}') = Q_{i,j}'$. Let

$$H_1'' := H_1' \cup \bigcup_{j \in [s_1]} F_{1,j}';$$

$$F_1' := \{F_{1,j}' : j \in [s_1]\}.$$

Since $H_i''$ is a copy of $\nabla_{(F,e_0)}(H_i, \psi_i) + s_i \cdot F$, we can assume (by redefining $\psi_2''$) that

\begin{equation}
\nabla_{(F,e_0)}(H_i'', \psi_i') \sim \nabla_{(F,e_0)}(M_h, \psi).
\end{equation}

Let $(H_i'', F_i'')$ be obtained by extending $H_i''$ with a copy of $\nabla_{(F,e_0)}(H_i', \psi_i')$ in $G$ (cf. Definition 8.16). We can assume that $H_i''$ and $H_i'''$ are vertex-disjoint.

Since $G$ is $(\xi, f, r)$-extendable, it is straightforward to find a copy $M'$ of $\nabla_{(F,e_0)}(M_h, \psi)$ in $G(r)$ which is vertex-disjoint from $H_1''$ and $H_2''$.

Since $H_1'''$ is a copy of $\nabla_{(F,e_0)}(H_1'', \psi_1')$, by (8.21) we have $H_i''' \sim M'$. Using Fact 8.14(ii) repeatedly, we can see that both $H_1'''$ and $H_2''$ are $F$-divisible. Together with Proposition 8.4(iii), this implies that $M'$ is $F$-divisible as well.

Let $T_1 := (H_1 - H) \cup H_1''$ and $T_2 := H_2 \cup H_2''$. Let

$$F_{1,1} := F_1 \cup F_2'' \cup F_{2,1}' \cup F_{2,2}''$$

We claim that $F_{1,1}, F_{1,2}, F_{2,1}, F_{2,2}$ are 2-well separated $F$-packings in $G$ such that

\begin{equation}
F_{1,1} := T_1 \cup H = H_1 \cup H_1'' \cup (H_1' - H_1') = F_1' \cup F_1'' \cup F_2' \cup F_2'' \quad \text{and} \quad F_{2,2} = T_2.
\end{equation}

(In particular, $T_1$ is a 2-well separated $(H, H_1''; F)$-transformer in $G$ and $T_2$ is a 2-well separated $(H_2'', \emptyset; F)$-transformer in $G$.) Indeed, we clearly have that $F_1, F_2, F_1', F_2'$ are 1-well separated $F$-packings in $G$, where $F_1' = H_1 - H$, $F_2' = H_2$, and $F_2'' = H_1'' - H_1'$. Moreover, by Fact 8.17, $F_1'$ and $F_2''$ are 1-well separated $F$-packings in $G$ with $F_2'' = H_1' - H_1'$. Note that

\begin{align}
T_1 \cup H_1'' = (H_1 \cup H_1'') \cup (H_1'' - H_1') = F_1' \cup F_1'' = F_{1,1}; \\
T_1 \cup H_1' = (H_1 - H) \cup (H_1' \cup H_1'') = F_1' \cup F_1'' = F_{1,2}; \\
T_2 \cup H_2'' = H_2 \cup (H_2'' \cup H_2') = F_2' \cup F_2'' = F_{2,2}; \\
T_2 \cup H_2' = (H_2 \cup H_2') \cup (H_2'' - H_2') = F_2' \cup F_2'' = F_{2,1}.'
To check that $F_1, F_2, F_{2,1}$ and $F_{2,2}$ are 2-well separated $F$-packings, by Fact 5.4(ii) it is now enough to show that $F_i$ and $F_i'$ are $(r+1)$-disjoint and that $F_1$ and $F_1''$ are $(r+1)$-disjoint.

Note that for all $F' \in F_i$ and $F'' \in F_i''$, we have $V(F') \subseteq V(H'_i)$ and $V(F'') \cap V(H'_i) = \emptyset$, thus $V(F') \cap V(F'') = \emptyset$. For all $F' \in F_i$ and $F'' \in F_i''$, we have $V(F') \subseteq V(H_i)$ and $|V(F'') \cap V(H_i)| \leq |V(F') \cap V(H_i^1)| \leq r$ by Fact 8.17, thus $|V(F') \cap V(F'')| \leq r$. This completes the proof of (8.22).

Let

$$O_r := H_1 \cup H_1'' \cup H_2 \cup H_2'';$$

$$O_{r+1,3} := F_{3,1}^{\leq (r+1)} \cup F_{3,2}^{\leq (r+1)} \cup F_{2,1}^{\leq (r+1)} \cup F_{2,2}^{\leq (r+1)}.$$ 

By Fact 5.4(i), $\Delta(O_{r+1,3}) \leq 8(f - r)$. Note that $H'_i, M' \subseteq G(r) - (O_r \cup H''_i)$. Thus, by Proposition 5.9(v) and Lemma 8.5, there exists a $(\kappa/3)$-well separated $(H''_i, M'; F)$-transformer $T_3$ in $G - (O_r \cup H''_i) - O_{r+1,3}$ with $\Delta(T_3) \leq \gamma n / 3$. Let $F_{3,1}$ and $F_{3,2}$ be $(\kappa/3)$-well separated $F$-packings in $G - (O_r \cup H''_i) - O_{r+1,3}$ such that $F_{3,1}^{(r)} = T_3 \cup H''_i$ and $F_{3,2}^{(r)} = T_3 \cup M'$.

Similarly, let $O_{r+1,4} := O_{r+1,3} \cup F_{3,1}^{(r+1)} \cup F_{3,2}^{(r+1)}$. By Fact 5.4(i), $\Delta(O_{r+1,4}) \leq (8 + 2\kappa/3)(f - r)$.

Note that $H''_i, M' \subseteq G(r) - (O_r \cup H''_i \cup T_3)$. Using Proposition 5.9(v) and Lemma 8.5 again, we can find a $(\kappa/3)$-well separated $(H''_i, M'; F)$-transformer $T_4$ in $G - (O_r \cup H''_i \cup T_3) - O_{r+1,4}$ with $\Delta(T_4) \leq \gamma n / 3$. Let $F_{4,1}$ and $F_{4,2}$ be $(\kappa/3)$-well separated $F$-packings in $G - (O_r \cup H''_i \cup T_3) - O_{r+1,4}$ such that of $F_{4,1}^{(r)} = T_4 \cup H''_i$ and $F_{4,2}^{(r)} = T_4 \cup M'$.

Let

$$A := T_1 \cup H''_i \cap T_3 \cup M' \cup T_4 \cup H''_2 \cup T_2;$$

$$F_0 := F_{1,2} \cup F_{3,2} \cup F_{4,1} \cup F_{2,1};$$

$$F_* := F_{3,1} \cup F_{4,2} \cup F_{2,2}.$$ 

Clearly, $A \subseteq G(r)$, and $\Delta(A) \leq \gamma n$. Moreover, $A$ and $H$ are edge-disjoint. Using (8.22), we can check that

$$F_0^{(r)} = F_{1,2}^{(r)} \cup F_{3,2}^{(r)} \cup F_{4,1}^{(r)} \cup F_{2,1}^{(r)} = (T_1 \cup H''_i \cap T_3 \cup M') \cup (T_4 \cup H''_2) \cup T_2 = A;$$

$$F_*^{(r)} = F_{3,1}^{(r)} \cup F_{4,2}^{(r)} \cup F_{2,2}^{(r)} = (H \cup T_1) \cup (H''_i \cup T_3) \cup (M' \cup T_4) \cup (H''_2 \cup T_2) = A \cup H.$$ 

By definition of $O_{r+1,3}$ and $O_{r+1,4}$, we have that $F_{1,2}, F_{3,2}, F_{4,1}, F_{2,1}$ are $(r+1)$-disjoint. Thus, $F_0$ is a $(2 \cdot \kappa/3 + 4)$-well separated $F$-packing in $G$ by Fact 5.4(ii). Similarly, $F_*$ is a $(2 \cdot \kappa/3 + 4)$-well separated $F$-packing in $G$. So $A$ is indeed a $\kappa$-well separated $F$-absorber for $H$ in $G$.

\end{proof}

9. PROOF OF THE MAIN THEOREMS

9.1. Main decomposition theorem. We can now deduce our main decomposition result for supercomplexes (modulo the proof of the Cover down lemma). The main ingredients for the proof of Theorem 4.7 are Lemma 7.4 (to find a vortex), Lemma 8.2 (to find absorbers for the possible leftovers in the final vortex set), and Lemma 7.5 (to cover all edges outside the final vortex set).

\begin{proof}[Proof of Theorem 4.7] We proceed by induction on $r$. The case $r = 1$ forms the base case of the induction and in this case we do not rely on any inductive assumption. Suppose that $r \in \mathbb{N}$ and that $(*)_i$ is true for all $i \in [r - 1]$.

We may assume that $1/n \ll 1/\kappa \ll \varepsilon$. Choose new constants $\kappa', m' \in \mathbb{N}$ and $\gamma, \mu > 0$ such that

$$1/n \ll 1/\kappa \ll \gamma \ll 1/m' \ll 1/\kappa' \ll \varepsilon \ll \mu \ll \xi, 1/f$$

and suppose that $F$ is a weakly regular $r$-graph on $f > r$ vertices.

Let $G$ be an $F$-divisible $(\varepsilon, \xi, f, r)$-supercomplex on $n$ vertices. We are to show the existence of a $\kappa$-well separated $F$-decomposition of $G$. By Lemma 7.4, there exists a $(2\sqrt{\varepsilon}, \mu, \xi - \varepsilon, f, r, m)$-vortex $U_0, U_1, \ldots, U_\ell$ in $G$ for some $\mu m' \leq m \leq m'$. Let $H_1, \ldots, H_\ell$ be an enumeration of all spanning $F$-divisible subgraphs of $G[U_\ell]^{(r)}$. Clearly, $s \leq 2^{(m)}$. We will now find edge-disjoint subgraphs $A_1, \ldots, A_\ell$ of $G^{(r)}$ and $\sqrt{\kappa}$-well separated $F$-packings $F_{1,0}, F_{1,1}, \ldots, F_{s,0}, F_{s,1}$ in $G$ such that for all $i \in [s]$ we have that

\end{proof}
(A1) $F_{i,0}^{(r)} = A_i$ and $F_{i,*}^{(r)} = A_i \cup H_i$;
(A2) $\Delta(A_i) \leq \gamma n$;
(A3) $A_i[U_1]$ is empty;
(A4) $F_{i,0}^{(r)} \subseteq G[U_1], F_{i,0}^{(*,r)}, \ldots, F_{i-1,0}^{(r)}, F_{i-1,0}^{(*,r)}, \ldots, F_{i,0}^{(r)}$ are $(r + 1)$-disjoint.

Suppose that for some $t \in [s]$, we have already found edge-disjoint $A_1, \ldots, A_{t-1}$ together with $F_{1,0}, F_{1,*}, \ldots, F_{t-1,0}, F_{t-1,*}$ that satisfy (A1)–(A4) (with $t - 1$ playing the role of $s$). Let

$$T_t := (G^{(r)}[U_1] - H_t) \cup \bigcup_{i \in [t-1]} A_i,$$

$$T'_t := G^{(r+1)}[U_1] \cup \bigcup_{i \in [t-1]} (F_{t,0}^{(r+1)} \cup F_{t,*}^{(r+1)}).$$

Clearly, $\Delta(T_t) \leq \mu n + s\gamma n \leq 2\mu n$ by (V2) and (A2). Also, $\Delta(T'_t) \leq \mu n + 2s\sqrt{r}(f - r) \leq 2\mu n$ by (V2) and Fact 5.4(i). Thus, applying Proposition 5.9(v) twice we see that $G_{\text{abs},t} := G - T_t - T'_t$ is still a $(\sqrt{m}, \varepsilon/2, f, r)$-supercomplex. Moreover, $H_t \subseteq G_{\text{abs},t}$ by (A3). Hence, by Lemma 8.2, there exists a $\sqrt{3r}$-well separated F-absorber $A_t$ for $H_t$ in $G_{\text{abs},t}$ with $\Delta(A_t) \leq \gamma n$. Let $F_{t,0}$ and $F_{t,*}$ be $\sqrt{3r}$-well separated F-packings in $G_{\text{abs},t} \subseteq G$ such that $F_{t,0}^{(r)} = A_t$ and $F_{t,*}^{(r)} = A_t \cup H_t$.

Clearly, $A_t$ is edge-disjoint from $A_1, \ldots, A_{t-1}$. Moreover, (A3) holds since $G_{\text{abs},t}[U_1] = H_t$ and $A_t$ is edge-disjoint from $H_t$, and (A4) holds with $t$ playing the role of $s$ due to the definition of $T'_t$.

Let $A^* := A_1 \cup \cdots \cup A_s$ and $T^* := \bigcup_{i \in [s]} (F_{i,0}^{(r+1)} \cup F_{i,*}^{(r+1)})$. We claim that the following hold:

(A1') for every $F$-divisible subgraph $H^*$ of $G[U_1]^{(r)}$, $A^* \cup H^*$ has an $s\sqrt{3r}$-well separated $F$-decomposition $F^*$ with $F^* \subseteq G[T^*]$;

(A2') $\Delta(A^*) \leq \varepsilon n$ and $\Delta(T^*) \leq 2s\sqrt{r}(f - r) \leq \varepsilon n$;

(A3') $A^*[U_1]$ and $T^*[U_1]$ are empty.

For (A1'), we have that $H^* = H_t$ for some $t \in [s]$. Then $F^* := F_{t,*} \cup \bigcup_{i \in [s]\setminus\{t\}} F_{i,0}$ is an $F$-decomposition of $A^* \cup H^* = (A_t \cup H_t) \cup \bigcup_{i \in [s]\setminus\{t\}} A_i$ by (A1) and since $H_t, A_1, \ldots, A_t$ are pairwise edge-disjoint. By (A4) and Fact 5.4(ii), $F^*$ is an $\varepsilon n$-well separated $F$-decomposition. We clearly have $F^* \subseteq G$ and $F^* \leq (r+1) \leq T^*$. Thus $F^* \subseteq G[T^*]$ and so (A1') holds. It is straightforward to check that (A2') follows from (A2) and Fact 5.4(i), and that (A3') follows from (A3) and (A4).

Let $G_{\text{almost}} := G - A^* - T^*$. By (A2') and Proposition 5.9(v), $G_{\text{almost}}$ is an $(\varepsilon \sqrt{r}, \varepsilon/2, f, r)$-supercomplex. Moreover, since $A^*$ must be $F$-divisible, we have that $G_{\text{almost}}$ is $F$-divisible. By (A3'), $U_1, \ldots, U_t$ is a $(2\varepsilon \sqrt{r}, \mu, \varepsilon - \varepsilon \sqrt{r}, f, r, m)$-vortex in $G_{\text{almost}}[U_1]$. Moreover, (A2') and Proposition 7.13 imply that $U_1$ is an $(\varepsilon \sqrt{3r}, \mu, \varepsilon/2, f, r)$-random in $G_{\text{almost}}$ and $U_1 \setminus U_2$ is an $(\varepsilon \sqrt{3r}, \mu(1 - \mu), \varepsilon/2, f, r)$-random in $G_{\text{almost}}$. Hence, $U_0, U_1, \ldots, U_t$ is still an $(\varepsilon \sqrt{3r}, \mu, \varepsilon/2, f, r, m)$-vortex in $G_{\text{almost}}$. Thus, by Lemma 7.5, there exists a $4\sqrt{r}$-well separated $F$-packing $F_{\text{almost}}$ in $G_{\text{almost}}$ which covers all edges of $G_{\text{almost}}$ except possibly some inside $U_t$. Let $H^* := (G_{\text{almost}} - F_{\text{almost}})^{(r)}[U_1]$. Since $H^*$ is $F$-divisible, $A^* \cup H^*$ has an $s\sqrt{3r}$-well separated $F$-decomposition $F^*$ with $F^* \subseteq G[T^*]$ by (A1'). Clearly,

$$G^{(r)} = G_{\text{almost}}^{(r)} \cup A^* = F_{\text{almost}}^{(r)} \cup H^* \cup A^* = F_{\text{almost}}^{(r)} \cup F^*(r),$$

and $F_{\text{almost}}$ and $F^*$ are $(r + 1)$-disjoint. Thus, by Fact 5.4(ii), $F_{\text{almost}} \cup F^*$ is a $(4\kappa' + s\sqrt{r})$-well separated $F$-decomposition of $G$, completing the proof.

$\square$

9.2. Resolvable partite designs. Perhaps surprisingly, it is much easier to obtain decompositions of complete partite $r$-graphs than of complete (non-partite) $r$-graphs. In fact, we can obtain (explicit) resolvable decompositions (sometimes referred to as Kirkman systems) in the partite setting using basic linear algebra. We believe that this result and the corresponding construction are of independent interest. Here, we will use this result to show that for every $r$-graph $F$, there is a weakly regular $r$-graph $F^*$ which is $F$-decomposable (see Lemma 9.2).

Let $G$ be a complex. We say that a $K_f^{(r)}$-decomposition $\mathcal{K}$ of $G$ is resolvable if $\mathcal{K}$ can be partitioned into $K_f^{(r-1)}$-decompositions of $G$, that is, $\mathcal{K} \leq (f)$ can be partitioned into sets $Y_1, \ldots, Y_f$
such that for each \( i \in [t] \), \( K_i := \{ G^{(r-1)}[Q] : Q \in Y_i \} \) is a \( K^{(r-1)}_f \)-decomposition of \( G \). Clearly, \( K_1, \ldots, K_t \) are \( r \)-disjoint.

Let \( K_{n \times k} \) be the complete \( k \)-partite complex with each vertex class having size \( n \). More precisely, \( K_{n \times k} \) has vertex set \( V_1 \cup \cdots \cup V_k \) such that \( |V_i| = n \) for all \( i \in [k] \) and \( e \in K_{n \times k} \) if and only if \( e \) is crossing, that is, intersects with each \( V_i \) in at most one vertex. Since every subset of a crossing set is crossing, this defines a complex.

**Theorem 9.1.** Let \( q \) be a prime power and \( 2f \leq q \). Then for every \( r \in [f-1] \), \( K_{q \times f} \) has a resolvable \( K^{(r)}_f \)-decomposition.

Let us first motivate the proof of Theorem 9.1. Let \( F \) be the finite field of order \( q \). Assume that each class of \( K_{q \times f} \) is a copy of \( F \). Suppose further that we are given a matrix \( A \in F^{(f-r)\times f} \) with the property that every \((f-r) \times (f-r)\)-submatrix is invertible. Identifying \( K^{(f)}_{q \times f} \) with \( F^{f} \) in the obvious way, we let \( K \) be the set of all \( Q \in K^{(f)}_{q \times f} \) with \( AQ = 0 \). Fixing the entries of \( r \) coordinates of \( Q \) (which can be viewed as fixing an \( r \)-set) transforms this into an equation \( A'Q' = b' \), where \( A' \) is an \((f-r) \times (f-r)\)-submatrix of \( A \). Thus, there exists a unique solution, which will translate into the fact that every \( r \)-set of \( K_{q \times f} \) is contained in exactly one \( f \)-set of \( K \), i.e., we have a \( K^{(r)}_f \)-decomposition.

There are several known classes of matrices over finite fields which have the desired property that every square submatrix is invertible. We use so-called Cauchy matrices, introduced by Cauchy [12], which are very convenient for our purposes. For an application of Cauchy matrices to coding theory, see e.g. [9].

Let \( F \) be a field and let \( x_1, \ldots, x_m, y_1, \ldots, y_n \) be distinct elements of \( F \). The Cauchy matrix generated by \((x_i)_{i \in [m]} \) and \((y_j)_{j \in [n]} \) is the \( m \times n \)-matrix \( A \in F^{m \times n} \) defined by \( a_{i,j} := (x_i - y_j)^{-1} \). Obviously, every submatrix of a Cauchy matrix is itself a Cauchy matrix. For \( m = n \), it is well known that the Cauchy determinant is given by the following formula (cf. [44]):

\[
\det(A) = \prod_{1 \leq i < j \leq n} (x_j - x_i)(y_i - y_j) / \prod_{1 \leq i < j \leq n} (x_i - y_j).
\]

In particular, every square Cauchy matrix is invertible.

**Proof of Theorem 9.1.** Let \( F \) be the finite field of order \( q \). Since \( 2f \leq q \), there exists a Cauchy matrix \( A \in F^{(f-r+1)\times f} \). Let \( \hat{a} \) be the final row of \( A \) and let \( A' \in F^{(f-r)\times f} \) be obtained from \( A \) by deleting \( \hat{a} \).

We assume that the vertex set of \( K_{q \times f} \) is \( F \times [f] \). Hence, for every \( e \in K_{q \times f} \), there are unique \( 1 \leq i_1 < \cdots < i_{|e|} \leq f \) and \( x_1, \ldots, x_{|e|} \in F \) such that \( e = \{(x_j, i_j) : j \in [|e|]\} \). Let

\[
I_e := \{i_1, \ldots, i_{|e|}\} \subseteq [f] \quad \text{and} \quad x_e := \begin{pmatrix} x_1 \\ \vdots \\ x_{|e|} \end{pmatrix} \in F^{|e|}.
\]

Clearly, \( Q \in K^{(f)}_{q \times f} \) is uniquely determined by \( x_Q \).

Define \( Y \subseteq K^{(f)}_{q \times f} \) as the set of all \( Q \in K^{(f)}_{q \times f} \) which satisfy \( A' \cdot x_Q = 0 \). Moreover, for each \( x^* \in F \), define \( Y_{x^*} \subseteq Y \) as the set of all \( Q \in Y \) which satisfy \( \hat{a} \cdot x_Q = x^* \). Clearly, \( \{Y_{x^*} : x^* \in F \} \) is a partition of \( Y \). Let \( K := \{K^{(r)}_{q \times f} | Q \in Y \} \) and \( K_{x^*} := \{K^{(r-1)}_{q \times f} | Q \in Y_{x^*} \} \) for each \( x^* \in F \). We claim that \( K \) is a \( K^{(r)}_f \)-decomposition of \( K_{q \times f} \) and that \( K_{x^*} \) is a \( K^{(r-1)}_f \)-decomposition of \( K_{q \times f} \) for each \( x^* \in F \).

For \( I \subseteq [f] \), let \( A_I \) be the \((f-r+1) \times |I|\)-submatrix of \( A \) obtained by deleting the columns which are indexed by \([f] \setminus I\). Similarly, for \( I \subseteq [f] \), let \( A'_{I'} \) be the \((f-r) \times |I|\)-submatrix of \( A' \) obtained by deleting the columns which are indexed by \([f] \setminus I\). Finally, for a vector \( x \in F^{|I|} \) and \( I \subseteq [f] \), let \( x_{I} \in F^{|I|} \) be the vector obtained from \( x \) by deleting the coordinates not in \( I \).

Observe that for all \( e \in K_{q \times f} \) and \( Q \in K^{(f)}_{q \times f} \), we have

\[
e \subseteq Q \quad \text{if and only if} \quad x_Q I_e = x_e.
\]
Consider $e \in K_{q \times f}^{(r)}$. By (9.1), the number of $Q \in Y$ containing $e$ is equal to the number of $x \in \mathbb{F}^f$ such that $A' \cdot x = 0$ and $x_{r_i} = x_e$, or equivalently, the number of $x' \in \mathbb{F}^{f-r}$ satisfying $A'_{f \setminus \ell_e} \cdot x_e + A'_{f} \cdot x' = 0$. Since $A'_{f \setminus \ell_e}$ is an $(f-r) \times (f-r)$-Cauchy matrix, the equation $A'_{f \setminus \ell_e} \cdot x' = -A'_{\ell_e} \cdot x_e$ has a unique solution $x' \in \mathbb{F}^{f-r}$, i.e. there is exactly one $Q \in Y$ which contains $e$. Thus, $K$ is a $K_{q \times f}^{(r)}$-decomposition of $K_{q \times f}$.

Now, fix $x^* \in \mathbb{F}$ and $e \in K_{q \times f}^{(r-1)}$. By (9.1), the number of $Q \in Y_{x^*}$ containing $e$ is equal to the number of $x \in \mathbb{F}^f$ such that $A' \cdot x = 0$, $a \cdot x = x^*$ and $x_{r_i} = x_e$, or equivalently, the number of $x' \in \mathbb{F}^{f-(r-1)}$ satisfying $A_{\ell_e} \cdot x_e + A_{f \setminus \ell_e} \cdot x' = \left( \begin{array}{c} 0 \\ x^* \end{array} \right)$. Since $A_{f \setminus \ell_e}$ is an $(f-r+1) \times (f-r+1)$-Cauchy matrix, this equation has a unique solution $x' \in \mathbb{F}^{f-r+1}$, i.e. there is exactly one $Q \in Y_{x^*}$ which contains $e$. Hence, $K_{x^*}$ is a $K_{q \times f}^{(r-1)}$-decomposition of $K_{q \times f}$.

Our application of Theorem 9.1 is as follows.

**Lemma 9.2.** Let $2 \leq r < f$. Let $F$ be any $r$-graph on $f$ vertices. There exists a weakly regular $r$-graph $F^*$ on at most $2f - f!$ vertices which has a 1-well separated $F$-decomposition.

**Proof.** Choose a prime power $q$ with $q! \leq q \leq 2f!$. Let $V(F) = \{v_1, \ldots, v_f\}$. By Theorem 9.1, there exists a resolvable $K_{f}^{(r)}$-decomposition $K$ of $K_{q \times f}$. Let the vertex classes of $K_{q \times f}$ be $V_1, \ldots, V_f$. Let $K_1, \ldots, K_f$ be a partition of $K$ into $K_{f}^{(r-1)}$-decompositions of $K_{q \times f}$. (We will only need $K_1, \ldots, K_f$.) We now construct $F^*$ with vertex set $V(K_{q \times f})$ as follows: Let $\pi_1, \ldots, \pi_f$ be an enumeration of all permutations on $[f]$. For every $i \in [f!]$ and $Q \in K_{q \times f}^{(r-1)}$, let $F_{i,Q}$ be a copy of $F$ with $V(F) = Q$ such that for every $j \in [f]$, the unique vertex in $Q \cap V(\pi_i(j))$ plays the role of $v_j$. Let

$$F^* := \bigcup_{i \in [f!], Q \in K_{q \times f}^{(r-1)}} F_{i,Q};$$

$$\mathcal{F} := \{F_{i,Q} : i \in [f!], Q \in K_{q \times f}^{(r-1)}\}.$$

Since $K_1, \ldots, K_f$ are $r$-disjoint, we have $|V(F^*) \cap V(F^{(y)})| < r$ for all distinct $F^*, F^{(y)} \in \mathcal{F}$. Thus, $\mathcal{F}$ is a 1-well separated $F$-decomposition of $F^*$.

We now show that $F^*$ is weakly regular. Let $i \in [r-1]_0$ and $S \in \binom{V(F)}{i}$. If $S$ is not crossing, then $|F^*(S)| = 0$, so assume that $S$ is crossing. If $i = r - 1$, then $S$ plays the role of every $(r-1)$-subset of $V(F)$ exactly $k$ times, where $k$ is the number of permutations on $[f]$ that map $[r-1]$ to $[r-1]$. Hence,

$$|F^*(S)| = |F| r^k = |F| r!(f-r+1)! =: s_{r-1}.$$

If $i < r - 1$, then $S$ is contained in exactly $c_i := \binom{f-i}{r-1-i} q^{r-1-i}$ crossing $(r-1)$-sets. Thus,

$$|F^*(S)| = \frac{s_{r-1} c_i}{r-i} =: s_i.$$

Therefore, $F^*$ is weakly $(s_0, \ldots, s_{r-1})$-regular. 

9.3. **Proofs of Theorems 1.1, 1.2, 1.4, 1.6 and 1.7.** We now prove our main theorems which guarantee $F$-decompositions in $r$-graphs of high minimum degree (for weakly regular $r$-graphs $F$, see Theorem 1.4), and $F$-designs in typical $r$-graphs (for arbitrary $r$-graphs $F$, see Theorem 1.1). We will also derive Theorems 1.2, 1.6 and 1.7.

We first prove the minimum degree version (for weakly regular $r$-graphs $F$). Instead of directly proving Theorem 1.4 we actually prove a stronger ‘local resilience version’. Let $\mathcal{H}_F(n, p)$ denote the random binomial $r$-graph on $[n]$ whose edges appear independently with probability $p$.

**Theorem 9.3 (Resilience version).** Let $p \in (0, 1]$ and $f, r \in \mathbb{N}$ with $f > r$ and let

$$c(f, r, p) := \frac{r! p^{r(f+r)}}{3 \cdot 14^r f^{2r}}.$$
Then the following holds whp for \( H \sim \mathcal{H}_r(n, p) \). For every weakly regular \( r \)-graph \( F \) on \( f \) vertices and any \( r \)-graph \( L \) on \( [n] \) with \( \Delta(L) \leq c(f, r, p)n \), \( H \triangle L \) has an \( F \)-decomposition whenever it is \( F \)-divisible.

The case \( p = 1 \) immediately implies Theorem 1.4.

**Proof.** Choose \( n_0 \in \mathbb{N} \) and \( \varepsilon > 0 \) such that \( 1/n_0 \ll \varepsilon \ll 1/f \) and let \( n \geq n_0 \),

\[
c' := 1.1 \cdot 2^{r(f+r)} \binom{f+r}{f-r} \left( f^{-r} \right) c(f, r, p), \quad \xi := 0.99/f!, \quad \xi' := 0.95 \xi p^{2r(f+r)} \left( f^{-r} \right) \left( \xi' - c' \right).
\]

Recall that the complete complex \( K_n \) is an \((\varepsilon, \xi, f, r)\)-supercomplex (cf. Example 4.9). Let \( H \sim \mathcal{H}_r(n, p) \). We can view \( H \) as a random subgraph of \( K_n^{(r)} \). By Corollary 5.19, the following holds whp for all \( L \subseteq K_n^{(r)} \) with \( \Delta(L) \leq c(f, r, p)n \):

\[
K_n[H \triangle L] \text{ is a } (3c + c', \xi' - c', f, r)\text{-supercomplex}.
\]

Note that \( c' \leq p^{2r(f+r)}(2\sqrt{c}/f)! \). Thus, \( 2(2\sqrt{c})^{-r} \cdot (3c + c') \leq \xi' - c' \). Lemma 4.4 now implies that \( K_n[H \triangle L] \) is an \((\varepsilon, \xi'', f, r)\)-supercomplex. Hence, if \( H \triangle L \) is \( F \)-divisible, it has an \( F \)-decomposition by Theorem 4.7.

Next, we derive Theorem 1.1. As indicated previously, we cannot apply Theorem 4.7 directly, but have to carry out two reductions. As shown in Lemma 9.2, we can ‘perfectly’ pack any given \( r \)-graph \( F \) into a weakly regular \( r \)-graph \( F^* \). We also need the following theorem, which we will prove later in Section 11. It allows us to remove a sparse \( F \)-decomposable subgraph \( L \) from an \( F \)-divisible \( r \)-graph \( G \) to achieve that \( G - L \) is \( F^* \)-divisible. Note that we do not need to assume that \( F^* \) is weakly regular.

**Lemma 9.4.** Let \( 1/n \ll \gamma \ll \xi \ll 1/f^* \) and \( r \in [f^* - 1] \). Let \( F \) be an \( r \)-graph. Let \( F^* \) be an \( r \)-graph on \( f^* \) vertices which has a 1-well separated \( F \)-decomposition. Let \( G \) be an \( r \)-graph on \( n \) vertices such that for all \( A \subseteq \binom{V(G)}{r-1} \) with \( |A| \leq \binom{f^*}{r-1} - 1 \), we have \( |\bigcap_{S \in A} G(S)| \geq \xi n \). Let \( O \) be an \((r + 1)\)-graph on \( V(G) \) with \( \Delta(O) \leq \gamma n \). Then there exists an \( F \)-divisible subgraph \( D \subseteq G \) with \( \Delta(D) \leq \gamma^{-2} \) such that the following holds: for every \( F \)-divisible \( r \)-graph \( H \) on \( V(G) \) which is edge-disjoint from \( D \), there exists a subgraph \( D^* \subseteq D \) such that \( H \cup D^* \) is \( F^* \)-divisible and \( D - D^* \) has a 1-well separated \( F \)-decomposition \( F \) such that \( F \leq (r+1) \) and \( O \) are edge-disjoint.

In particular, we will apply this lemma when \( G \) is \( F \)-divisible and thus \( H := G - D \) is \( F \)-divisible. Then \( L := D - D^* \) is a subgraph of \( G \) with \( \Delta(L) \leq \gamma^{-2} \) and has a 1-well separated \( F \)-decomposition \( F \) such that \( F \leq (r+1) \) and \( O \) are edge-disjoint. Moreover, \( G - L = H \cup D^* \) is \( F^* \)-divisible.

We can deduce the following corollary from the case \( F = K_n^{(r)} \) of Lemma 9.4.

**Corollary 9.5.** Let \( 1/n \ll \gamma \ll \xi \ll 1/f \) and \( r \in [f - 1] \). Let \( F \) be an \( r \)-graph on \( f \) vertices. Let \( G \) be an \( r \)-graph on \( n \) vertices such that for all \( A \subseteq \binom{V(G)}{r-1} \) with \( |A| \leq \binom{f}{r-1} - 1 \), we have \( |\bigcap_{S \in A} G(S)| \geq \xi n \). Then there exists a subgraph \( D \subseteq G \) with \( \Delta(D) \leq \gamma^{-2} \) such that the following holds: for any \( r \)-graph \( H \) on \( V(G) \) which is edge-disjoint from \( D \), there exists a subgraph \( D^* \subseteq D \) such that \( H \cup D^* \) is \( F \)-divisible.

In particular, using \( H := G - D \), there exists a subgraph \( L := D - D^* \subseteq G \) with \( \Delta(L) \leq \gamma^{-2} \) such that \( G - L = H \cup D^* \) is \( F \)-divisible.

**Proof.** Apply Lemma 9.4 with \( F, K_n^{(r)} \) playing the roles of \( F^*, F \).

We now prove the following theorem, which immediately implies the case \( \lambda = 1 \) of Theorem 1.1.

**Theorem 9.6.** Let \( 1/n \ll \gamma, 1/k \ll c, p, 1/f \) and \( r \in [f - 1] \), and

\[
c \leq p^h/(q^*4^q), \quad \text{where } h := 2^r \binom{q + r}{r} \quad \text{and } q := 2f \cdot f!.
\]
Let $F$ be any $r$-graph on $f$ vertices. Suppose that $G$ is a $(c, h, p)$-typical $F$-divisible $r$-graph on $n$ vertices. Let $O$ be an $(r + 1)$-graph on $V(G)$ with $\Delta(O) \leq \gamma n$. Then $G$ has a $\kappa$-well separated $F$-decomposition $F$ such that $F \subseteq (r+1)$ and $O$ are edge-disjoint.

**Proof.** By Lemma 9.2, there exists a weakly regular $r$-graph $F^*$ on $f^* \leq q$ vertices which has a 1-separated $F$-decomposition.

By Lemma 9.4 (with $0.5p^{(r^*+1)}$ playing the role of $\xi$), there exists a subgraph $L \subseteq G$ with $\Delta(L) \leq \gamma^{-2}$ such that $G - L$ is $F^*$-divisible and $L$ has a 1-separated $F$-decomposition $F_{\text{div}}$ such that $F_{\text{div}} \subseteq (r+1)$ and $O$ are edge-disjoint. By Fact 5.4(i), $\Delta(F_{\text{div}}) \leq f - r$. Let

$$G' := G^* - L - F_{\text{div}} \subseteq (r+1) - O.$$  

By Example 4.10, $G'^*_{\text{div}}$ is an $(\varepsilon, \xi, f^*, r)$-supercomplex, where $\varepsilon := 2f^*-r+1c/(f^*-r)!$ and $\xi := (1 - 2f^*-r+1c)p^{2(r^*+1)/f^*}$. Observe that assumption (9.2) now guarantees that $2(2\sqrt{\varepsilon})\varepsilon \leq \xi$. Thus, by Lemma 4.4, $G'^*_{\text{div}}$ is a $(\gamma, \xi', f^*, r)$-supercomplex, where $\xi' := 0.9(1/4)(r^*+r)\xi$. By Proposition 5.9(v), we have that $G'$ is a $(\sqrt{\gamma}, \xi'/2, f^*, r)$-supercomplex. Moreover, $G'$ is $F^*$-divisible. Thus, by Theorem 4.7, $G'$ has a $(\kappa-1)$-well separated $F^*$-decomposition $F^*$. Since $F^*$ has a 1-separated $F$-decomposition, we can conclude that $G'$ has a $(\kappa-1)$-well separated $F$-decomposition $F_{\text{complex}}$. Let $F := F_{\text{div}} \cup F_{\text{complex}}$. By Fact 5.4(ii), $F$ is a $\kappa$-well separated $F$-decomposition of $G$. Moreover, $F \subseteq (r+1)$ and $O$ are edge-disjoint. $\square$

We next derive Theorem 1.1 from Theorem 9.6 and Corollary 9.5.

**Proof of Theorem 1.1.** Choose a new constant $\kappa \in \mathbb{N}$ such that

$$1/n < \gamma < 1/\kappa < c, p, 1/f.$$  

Suppose that $G$ is a $(c, h, p)$-typical $(F, \lambda)$-divisible $r$-graph on $n$ vertices. Split $G$ into two subgraphs $G'_1$ and $G'_2$ which are both $(c + \gamma, h, p/2)$-typical (a standard Chernoff-type bound shows that a random splitting of $G$ yields the desired property).

By Corollary 9.5 (applied with $G'_2, 0.5(p/2)^{(r-1)}$ playing the roles of $G, \xi$), there exists a subgraph $L^* \subseteq G'_2$ with $\Delta(L^*) \leq \kappa$ such that $G_2 := G'_2 - L^*$ is $F$-divisible. Let $G_1 := G'_1 \cup L^* = G - G_2$. Clearly, $G_1$ is still $(F, \lambda)$-divisible. By repeated applications of Corollary 9.5, we can find edge-disjoint subgraphs $L_1, \ldots, L_\lambda$ of $G_1$ such that $R_i := G_1 - L_i$ is $F$-divisible and $\Delta(L_i) \leq \kappa$ for all $i \in [\lambda]$.

Indeed, suppose that we have already found $L_1, \ldots, L_{i-1}$. Then $\Delta(L_1 \cup \cdots \cup L_{i-1}) \leq \lambda \kappa \leq \gamma^{1/2}n$ (recall that $\lambda \leq \gamma n$). Thus, by Corollary 9.5, there exists a subgraph $L_i \subseteq G'_1 - (L_1 \cup \cdots \cup L_{i-1})$ with $\Delta(L_i) \leq \kappa$ such that $G_1 - L_i$ is $F$-divisible.

Let $G''_1 := G_2 \cup L_1 \cup \cdots \cup L_\lambda$. We claim that $G''_1$ is $F$-divisible. Indeed, let $S \subseteq V(G)$ with $|S| \leq r - 1$. We then have that $|G''_1(S)| = |G_2(S)| + \sum_{i \in [\lambda]} |(G_1 - R_i)(S)| = |G_2(S)| + \lambda |G_1(S)| - \sum_{i \in [\lambda]} \deg(F)|S|.$

Since $G'_1$ and $G'_2$ are both $(c + \gamma, h, p/2)$-typical and $L^*(L_1 \cup \cdots \cup L_\lambda) \leq 2\gamma^{1/2}n$, we have that each of $G_2, G''_1, R_1, \ldots, R_\lambda$ is $(c + \gamma^{1/2}, h, p/2)$-typical (and they are $F$-divisible by construction).

Using Theorem 9.6 repeatedly, we can thus find $\kappa$-well separated $F$-decompositions $F_1, \ldots, F_{\lambda-1}$ of $G_2$, a $\kappa$-well separated $F$-decomposition $F'$ of $G''_1$, and for each $i \in [\lambda]$, a $\kappa$-well separated $F$-decomposition $F_i$ of $R_i$. Moreover, we can assume that all these decompositions are pairwise $(r + 1)$-disjoint. Indeed, this can be achieved by choosing them successively: Let $O$ consist of the $(r + 1)$-sets which are covered by the decompositions we have already found. Then by Fact 5.4(i), we have that $\Delta(O) \leq 2\lambda \cdot \kappa (f - r) \leq \gamma^{1/2}n$. Hence, using Theorem 9.6, we can find the next $\kappa$-well separated $F$-decomposition which is $(r + 1)$-disjoint from the previously chosen ones.

Then $F := F' \cup \bigcup_{i \in [\lambda-1]} F_i \cup \bigcup_{i \in [\lambda]} F_i$ is the desired $(F, \lambda)$-design. Indeed, every edge of $G_1 - (L_1 \cup \cdots \cup L_\lambda)$ is covered by each of $F'_1, \ldots, F'_\lambda$. For each $i \in [\lambda]$, every edge of $L_i$ is covered by $F^*$ and each of $F'_1, \ldots, F'_{i-1}, F'_{i+1}, \ldots, F'_\lambda$. Finally, every edge of $G_2$ is covered by each of $F_1, \ldots, F_{\lambda-1}$ and $F^*$. $\square$
Using the same strategy, a similar result which holds in the more general setting of supercomplexes can be obtained by using Corollary 6.10 instead of Corollary 9.5.

Theorem 1.2 is an immediate consequence of Theorem 9.6 and Corollary 9.5.

**Proof of Theorem 1.2.** Apply Corollary 9.5 (with \( G, 0.5p^{(r-1)} \)) playing the roles of \( G, \xi \) to find a subgraph \( L \subseteq G \) with \( \Delta(L) \leq C \) such that \( G - L \) is \( F \)-divisible. It is easy to see that \( G - L \) is \((1.1c, h, p)\)-typical. Thus, we can apply Theorem 9.6 to obtain an \( F \)-decomposition \( \mathcal{F} \) of \( G - L \).

**Proof of Theorem 1.7.** By Example 4.12, we have that \( G^{**} \) is an \((0.01\xi, 0.99\xi, f, 1)\)-supercomplex. Moreover, since \( f \mid n, G^{**} \) is \( K_f^{(1)} \)-divisible. Thus, by Corollary 4.14, \( G^{**} \) has \( 0.01\xi n^{f-1} \) \( f \)-disjoint \( K_f^{(1)} \)-decompositions, i.e., \( G \) has \( 0.01\xi n^{f-1} \) edge-disjoint perfect matchings.

Finally, we also prove Theorem 1.6, which is an easy corollary of Theorem 1.1.

**Proof of Theorem 1.6.** Choose \( c, h, n_0 \) such that \( 1/n_0 < c < 1/h < p, 1/f \). Let \( K = \{ F_1, \ldots, F_t \} \). Thus \( t \leq 2r^{(r)} \). Let \( F^* = F_1 + \cdots + F_t \) and let \( a_1, \ldots, a_t \) be integers such that \( e := \gcd(\{|F_1|, \ldots, |F_t|\}) = a_1|F_1| + \cdots + a_t|F_t| \).

Now, assume that \( G \) is \((c, h, p)\)-typical and \( K \)-divisible. In particular, \( |G| \equiv e \mod |F^*| \) for some \( x \in \mathbb{Z} \). With the above, \( |G| \equiv \sum_{i \in \{0\}} a_i|F_i| \mod |F^*| \) for some integers \( a'_i \). Clearly, we may assume that \( 0 \leq a'_i < |F^*| \). Let \( F_0 \) be a set of \( a'_i \) copies of \( F_i \) in \( G \) for all \( i \in \{0\} \), all edge-disjoint. Let \( G' := G - F_0^{(r)} \). It is easy to check that \( G' \) is \( F^* \)-divisible. Thus, since \( G' \) is \((2c, h, p)\)-typical, Theorem 1.1 implies that \( G' \) has an \( F^* \)-decomposition. In particular, \( G' \) has a \( K \)-decomposition \( \mathcal{F}_1 \). Finally, \( F_0 \cup \mathcal{F}_1 \) is a \( K \)-decomposition of \( G \).

10. Covering down

The aim of this section is to prove the Cover down lemma (Lemma 7.7). Suppose that \( G \) is a supercomplex and \( U \) is a ‘random-like’ subset of \( V(G) \). The Cover down lemma shows the existence of a ‘cleaning graph’ \( H^* \) so that for any sparse leftover graph \( L^* \), \( G[H^* \cup L^*] \) has an \( F \)-packing covering all edges of \( H^* \cup L^* \) except possibly some inside \( U \).

We now briefly sketch how one can attempt to construct such a graph \( H^* \). As in Section 7.1, for an edge \( e \), we refer to \( |e \cap U| \) as its type. For the moment, suppose that \( H^* \) and \( L^* \) are given. A natural way (for divisibility reasons) to try to cover all edges of \( H^* \cup L^* \) which are not inside \( U \) is to first cover all type-0-edges, then all type-1-edges, etc. and finally all type-\((r-1)\)-edges. It is comparatively easy to cover all type-0-edges. The reason for this is that a type-0-edge can be covered by a copy of \( F \) that contains no other type-0-edge. Thus, if \( H^* \) is a random subgraph of \( G^{(r)} - G^{(r)}[V(G) \setminus U] \), then every type-0-edge (from \( L^* \)) is contained in many copies of \( F \). Since \( \Delta(L^*) \) is very small, this allows us to apply Corollary 6.9 in order to cover all type-0-edges with edge-disjoint copies of \( F \).

The situation is very different for edges of higher types. Suppose that for some \( i \in \{r-1\} \), we have already covered all edges of types \( 0, \ldots, r-i-1 \) and now want to cover all edges of type \( r-i \). Every such edge contains a unique \( S \in \binom{V(G \setminus U)}{i} \). As indicated in Section 7.1, we seek to cover all edges containing a fixed \( S \in \binom{V(G \setminus U)}{i} \) simultaneously using Proposition 7.9 as follows: Let \( T \in \binom{V^*(F)}{i} \). Roughly speaking, for every \( S \in \binom{V(G \setminus U)}{i} \), we reserve a random subgraph \( H_S \) of \( G[S][U]^{(r-i)} \) and protect all the \( H_S \)’s when applying the nibble. Let \( L \) be the leftover resulting from this application and let \( L_S := L(S) \). Assuming that there are no more leftover edges of types \( 0, \ldots, r-i-1 \) implies that \( L_S \subseteq G(S)[U]^{(r-i)} \) and that \( H_S \cup L_S \) is \( F(T) \)-divisible. We want to use \((*)_{r-i} \) inductively to find a well separated \( F(T) \)-decomposition \( \mathcal{F}_S \) of \( H_S \cup L_S \) (provided that \( H_S \cup L_S \) is quasirandom). Using Proposition 7.9, \( \mathcal{F}_S \) can then be ‘extended’ to an \( F \)-packing \( S \cup \mathcal{F}_S \) which covers all edges that contain \( S \). The hope is that the \( H_S \)’s do not intersect too much, so that it is possible to find an \( F(T) \)-decomposition \( \mathcal{F}_S \) for each \( S \) such that the extended
F-packings $S \in \mathcal{F}_S$ are r-disjoint. Their union would then yield an F-packing covering all edges of type $r - i$.

There are two natural candidates for selecting $H_S$:

(A) Choose $H_S$ by including every edge of $G(S)[U]'(r-i)$ with probability $\nu$.

(B) Choose a random subset $U_S$ of $U$ of size $\rho|U|$ and let $H_S := G(S)'(r-i)[U_S]$.

The advantage of Strategy (A) is that $H_S \cup L_S$ is quasirandom if $L_S$ is sparse. This is not the case for (B): even if the maximum degree of $L_S$ is sublinear, its edges might be spread out over the whole of $U$ (while $H_S$ is restricted to $U_S$). Unfortunately, when pursuing Strategy (A), the $H_S$ intersect too much, so it is not clear how to find the desired decompositions due to the interference between different $H_S$. However, it turns out that under the additional assumption that $V(L_S) \subseteq U_S$, Strategy (B) does work. We call the corresponding result the ‘Localised cover down lemma’ (Lemma 10.8).

We will combine both strategies as follows: For each $S$, we will choose $H_S$ as in (A) and $U_S$ as in (B) and let $J_S := G(S)'(r-i)[U_S]$. In a first step we use $H_S$ to find an $F(T)$-packing covering all edges $e \in H_S \cup L_S$ with $e \not\subseteq U_S$, and then afterwards we apply the Localised cover down lemma to cover all remaining edges. Note that the first step resembles the original problem: We are given a graph $H_S \cup L_S$ on $U$ and want to cover all edges that are not inside $U_S \subseteq U$. But the resulting types are now more restricted. This enables us to prove a more general Cover down lemma, the ‘Cover down lemma for setups’ (Lemma 10.24), by induction on $r - i$, which will allow us to perform the first step in the above combined strategy for all $S$ simultaneously.

### 10.1. Systems and focuses

In this subsection, we prove the Localised cover down lemma, which shows that Strategy (B) works under the assumption that each $L_S$ is ‘localised’.

**Definition 10.1.** Given $i \in \mathbb{N}_0$, an i-system in a set $V$ is a collection $S$ of distinct subsets of $V$ of size $i$. A subset of $V$ is called $S$-important if it contains some $S \in S$, otherwise we call it $S$-unimportant. We say that $\mathcal{U} = \{U_S\}_{S \in S}$ is a focus for $S$ if for each $S \in S$, $U_S$ is a subset of $V \setminus S$.

**Definition 10.2.** Let $G$ be a complex and $S$ an i-system in $V(G)$. We call $G$ r-exclusive with respect to $S$ if every $e \in G$ with $|e| \geq r$ contains at most one element of $S$. Let $\mathcal{U}$ be a focus for $S$. If $G$ is r-exclusive with respect to $S$, the following functions are well-defined: For $r' \geq r$, let $\mathcal{E}_{r'}$ denote the set of $S$-important $r'$-sets in $G$. Define $\tau_{r'} : \mathcal{E}_{r'} \to [r' - i]_0$ as $\tau_{r'}(e) := |e \cap U_S|$, where $S$ is the unique $S \in S$ contained in $e$. We call $\tau_{r'}$ the type function of $G^{(r')}, S, \mathcal{U}$.

**Fact 10.3.** Let $r \in \mathbb{N}$ and $i \in [r' - i]_0$. Let $G$ be a complex and $S$ an i-system in $V(G)$. Let $\mathcal{U}$ be a focus for $S$ and suppose that $G$ is r-exclusive with respect to $S$. For $r' \geq r$, let $\tau_{r'} : \mathcal{E}_{r'} \to [r' - i]_0$ denote the type function of $G^{(r')}, S, \mathcal{U}$. Let $e \in G$ with $|e| \geq r$ be $S$-important and let $\mathcal{E}' := \mathcal{E}_{r'} \cap (\mathcal{E}_{r'} \cap (e))$.

Then we have

(i) $\max_{e' \in \mathcal{E}'} \tau_{r'}(e') \leq \tau_{|e|}(e) \leq |e| - r + \min_{e' \in \mathcal{E}'} \tau_{r'}(e')$,

(ii) $\min_{e' \in \mathcal{E}'} \tau_{r'}(e') = \max\{r + \tau_{|e|}(e) - |e|, 0\}$.

**Proof.** Let $S \subseteq e$ with $S \in S$. Clearly, for every $S$-important $r'$-subset $e'$ of $e$, $S$ is the unique element from $S$ that $e'$ contains. For any such $e'$, we have $\tau_{|e|}(e) = |e' \cap U_S| \geq |e' \cap U_S| = \tau_{r'}(e')$, implying the first inequality of (i). Also, $|e| - \tau_{|e|}(e) = |e \setminus U_S| \geq |e' \setminus U_S| = r - \tau_{r'}(e')$, implying the second inequality of (i).

This also implies that $\min_{e' \in \mathcal{E}'} \tau_{r'}(e') \geq \max\{r + \tau_{|e|}(e) - |e|, 0\}$. To see the converse, note that $|e \setminus U_S| = |e| - \tau_{|e|}(e)$. Hence, we can choose an r-set $e' \subseteq e$ with $S \subseteq e'$ and $|e' \setminus U_S| = \min\{|e| - \tau_{|e|}(e), r\}$. Note that $e' \in \mathcal{E}'$ and $\tau_{r'}(e') = r - |e' \setminus U_S| = r - \min\{|e| - \tau_{|e|}(e), r\} = \max\{r + \tau_{|e|}(e) - |e|, 0\}$. This completes the proof of (ii).

**Definition 10.4.** Let $G$ be a complex and $S$ an i-system in $V(G)$. Let $\mathcal{U}$ be a focus for $S$ and suppose that $G$ is r-exclusive with respect to $S$. For $i' \in \{i + 1, \ldots, r - 1\}$, we define $\mathcal{T}$ as the set of all i'-subsets $T$ of $V(G)$ which satisfy $S \subseteq T \subseteq e \setminus U_S$ for some $S \in S$ and $e \in G^{(r)}$. We call $\mathcal{T}$ the $i'$-extension of $S$ in $G$ around $\mathcal{U}$. 

\[2\]
To see (i), suppose, for a contradiction, that there is some element. On the other hand, we may have $|T| < |S|$. Note that $U := \{ T \in \mathcal{T} : \emptyset \}
$ is a focus for $T$ as $T \cap T = \emptyset$ for all $T \in \mathcal{T}$.

The following proposition contains some basic properties of $i'$-extensions.

**Proposition 10.5.** Let $0 \leq i < i' < r$. Let $G$ be a complex and $S$ an $i$-system in $V(G)$. Let $U$ be a focus for $S$ and suppose that $G$ is $r$-exclusive with respect to $S$. Let $T$ be the $i'$-extension of $S$ in $G$ around $U$. For $r' \geq r$, let $\tau_{r'}$ be the type function of $G^{(r')}$, $S, U$. Then the following hold for $G' := G - \{ e \in G^{(r')} : e \text{ is $S$-important and } \tau_{r'}(e) < r - i' \}$:

(i) $G'$ is $r$-exclusive with respect to $T$;
(ii) for all $e \in G$ with $|e| \geq r$, we have $e \notin G' \iff e$ is $S$-important and $\tau_{|e|}(e) < |e| - i'$;

(iii) for $r' \geq r$, the $T$-important elements of $G^{(r')}$ are precisely the elements of $\tau_{r'}^{-1}(r' - i')$.

**Proof.** To see (i), suppose, for a contradiction, that there is some $e' \in G'$ with $|e'| \geq r$ and distinct $T, T' \in \mathcal{T}$ such that $e'$ contains both $T$ and $T'$. Let $S := T \cap S$ and $S' := T' \cap S$. Clearly, $S, S' \subseteq e' \subseteq G$. Since $G$ is $r$-exclusive with respect to $S$, we must have $S = S'$ and thus $U_S = U_S$. Since $T$ and $T'$ are distinct, we have that $|T \cup T'| > i'$. Let $e$ be a subset of $e'$ of size $r$ containing $S$ and at least $i' + 1$ vertices from $T \cup T'$. Since $e \subseteq e' \subseteq G'$, we must have $e \in G^{(r')}$.

On the other hand, since $S \subseteq e$, $e$ is $S$-important. However, as $T \cup T' \subseteq V(G) \setminus U_S$, we have $\tau_r(e) = |e| = |e \cap U_S| < r - i'$, contradicting the definition of $G'$.

For (ii), let $E_e$ be the set of $S$-important $r$-sets in $e$. By definition of $G'$, we have $e \notin G'$ if and only if $e$ is $S$-important, $E_e \neq \emptyset$ and $\min_{e \in E_e} \tau_r(e') < r - i'$. Then Fact 10.3(ii) implies the claim.

Finally, we prove (iii). Suppose first that $e \in G^{(r')}$ is $T$-important. Clearly, we have $\tau_r(e) \leq r' - i'$. Also, since $e$ must also be $S$-important, but $e \notin G'$, (ii) implies that $\tau_r(e) \geq r' - i'$. Hence, $e \in \tau_r^{-1}(r' - i')$. Now, suppose that $e \in \tau_r^{-1}(r' - i')$. By (ii), we have $e \in G'$ and it remains to show that $e$ is $T$-important. Since $e$ is $S$-important, there is a unique $S \subseteq e$ such that $S \subseteq e$. Let $T := e \setminus U_S$. Clearly, $S \subseteq T \subseteq e \setminus U_S$. Moreover, $|T| = |e| - |e \cap U_S| = r' - \tau_r(e) = i'$. Thus, $T \in \mathcal{T}$, implying that $e$ is $T$-important. \( \square \)

Let $Z_{r,i}$ be the set of all quadruples $(z_0, z_1, z_2, z_3) \in \mathbb{N}_0^4$ such that $z_0 + z_1 < i$, $z_0 + z_3 < i$ and $z_0 + z_1 + z_2 + z_3 = r$. Clearly, $|Z_{r,i}| \leq (r + 1)^3$, and $Z_{r,i} = \emptyset$ if $i = 0$.

**Definition 10.6.** Let $V$ be a set of size $n$, let $S$ be an $i$-system in $V$ and let $U$ be a focus for $S$. We say that $U$ is an $\mu$-focus for $S$ if each $U_S \in \mathcal{U}$ has size $\mu n \pm n^{2/3}$. For all $S \in \mathcal{S}$, $z = (z_0, z_1, z_2, z_3) \in Z_{r,i}$, and all $(z_1 + z_2 - 1)$-sets $b \subseteq V \setminus S$, define

$\mathcal{J}^b_{z,1} := \{ S' \in S : |S \cap S'| = z_0, b \subseteq S' \cup U_S, |U_S \cap S| \geq z_3 \}$,

$\mathcal{J}^b_{z,2} := \{ S' \in \mathcal{J}^b_{z,1} : |b \cap S'| = z_1 \}$,

$\mathcal{J}^b_{z,2} := \{ S' \in \mathcal{J}^b_{z,1} : |b \cap S'| = z_1 - 1, |U_S \cap (S' \setminus b) \} \geq 1 \}$.

We say that $U$ is a $(\rho, r, \mu)$-focus for $S$ if

(F1) each $U_S$ has size $\rho_S n \pm n^{2/3}$;

(F2) $|U_S \cup U_{S'}| \leq 2\rho n$ for distinct $S, S' \in \mathcal{S}$;

(F3) for all $S \in \mathcal{S}$, $z = (z_0, z_1, z_2, z_3) \in Z_{r,i}$ and $(z_1 + z_2 - 1)$-sets $b \subseteq V \setminus S$, we have

$|\mathcal{J}^b_{z,1}| \leq 2^{sr} \rho^{z_2 + z_3, z_0 - z_1 - 1}$,

$|\mathcal{J}^b_{z,2}| \leq 2^{sr} \rho^{z_2 + z_3, z_0 - z_1 + 1}$. 

The sets \( S' \) in \( \mathcal{J}_{S,1}^b \) and \( \mathcal{J}_{S,2}^b \) are those which may give rise to interference when covering the edges containing \( S \). (F3) ensures that there are not too many of them. The next lemma states that a suitable random choice of the \( U_S \) yields a \((\rho_{\text{size}}, \rho, r)\)-focus.

**Lemma 10.7.** Let \( 1/n < \rho < \rho_{\text{size}}, 1/r \) and \( i \in [r - 1] \). Let \( V \) be a set of size \( n \), let \( S \) be an \( i \)-system in \( V \) and let \( U = (U_S^i)_{S \in S} \) be a \( \rho_{\text{size}} \)-focus for \( S \). Let \( U = (U_S)_{S \in S} \) be a random focus obtained as follows: independently for all pairs \( S \in S \) and \( x \in U_S \), retain \( x \) in \( U_S \) with probability \( \rho \). Then \( \mathbb{P}(U) \) is a \((\rho_{\text{size}}, \rho, r)\)-focus for \( S \).

**Proof.** Clearly, \( U_S \subseteq V \setminus S \) for all \( S \in S \).

**Step 1:** Probability estimates for (F1) and (F2)

For \( S \in S \), Lemma 5.10(i) implies that with probability at least \( 1 - 2e^{-0.5|U_S|^1/3} \), we have
\[
|U_S| = \mathbb{E}(|U_S|) \pm 0.5|U_S|^2/3 = \rho \rho_{\text{size}} n \pm (\rho n^2/3 + 0.5|U_S|^2/3).
\]
Thus, with probability at least \( 1 - e^{-n^1/4} \), (F1) holds.

Let \( S, S' \in \mathcal{S} \) be distinct. If \( |U_S^i \cap U_{S'}^i| \leq \rho^2 n \), then we surely have \( |U_S \cap U_{S'}| \leq \rho^2 n \), so assume that \( |U_S^i \cap U_{S'}^i| \geq \rho^2 n \). Lemma 5.10(i) implies that with probability at least \( 1 - 2e^{-2\rho^3|U_S^i \cap U_{S'}^i|} \), we have
\[
|U_S \cap U_{S'}| \leq \mathbb{E}(|U_S \cap U_{S'}|) + 2\rho^3 |U_S^i \cap U_{S'}^i| \leq 2\rho^2 n.
\]
Thus, with probability at least \( 1 - e^{-n^{1/2}} \), (F2) holds.

**Step 2:** Probability estimates for (F3)

Now, fix \( S \in S \), \( z = (z_0, z_1, z_2, z_3) \in \mathbb{Z}_{r,i} \) and an \((z_1 + z_2 - 1)\)-set \( b \subseteq V \setminus S \). In order to estimate \( |J_{S,z,1}^b| \) and \( |J_{S,z,2}^b| \), define
\[
\mathcal{J}^i := \{ S' \in \mathcal{S} : |S \cap S'| = z_0, |b \cap S'| = z_1 \},
\]
\[
\mathcal{J}^n := \{ S' \in \mathcal{S} : |S \cap S'| = z_0, |b \cap S'| = z_1 - 1 \}.
\]
Clearly, \( \mathcal{J}_{S,z,1}^b \subseteq \mathcal{J}^i \) and \( \mathcal{J}_{S,z,2}^b \subseteq \mathcal{J}^n \). Moreover, since \( b \cap S = \emptyset \), we have that
\[
|\mathcal{J}^i| \leq \binom{i}{z_0} \binom{z_1 + z_2 + 2 - 1}{z_1} n^{i - z_0 - z_1} \leq 2^r n^{i - z_0 - z_1},
\]
\[
|\mathcal{J}^n| \leq \binom{i}{z_0} \binom{z_1 + z_2 - 1}{z_1 - 1} n^{i - z_0 - z_1 + 1} \leq 2^r n^{i - z_0 - z_1 + 1}.
\]
Consider \( S' \in \mathcal{J}^i \). By the random choice of \( U_{S'} \) and since \( b \cap S = \emptyset \), we have that
\[
\mathbb{P}(S' \in \mathcal{J}_{S,z,1}^b) = \mathbb{P}(b \setminus S' \subseteq U_{S'}, |U_{S'} \cap S| \geq z_0) = \mathbb{P}(b \setminus S' \subseteq U_{S'}) \cdot \mathbb{P}(|U_{S'} \cap S| \geq z_3).
\]
Note that \( \mathbb{P}(b \setminus S' \subseteq U_{S'}) \leq \rho^{z_2 - 1} \) since \( |b \setminus S'| = z_2 - 1 \). Moreover, \( \mathbb{P}(|U_{S'} \cap S| \geq z_3) \leq \left( \frac{1}{z_3} \right) \rho^{z_3} \leq 2^r \rho^{z_3} \).

Hence, \( \mathbb{E}(|\mathcal{J}_{S,z,1}^b|) \leq 2^{r+2}(\rho^{z_2} + 1) 2^r n^{i - z_0 - z_1} \). Since \( i - z_0 - z_1 \geq 1 \) and \( U_{S'} \) and \( U_{S''} \) are chosen independently for any two distinct \( S', S'' \in \mathcal{J}^i \), Lemma 5.10(iii) implies that
\[
\mathbb{P}(|\mathcal{J}_{S,z,1}^b| \geq 2^r \rho^{z_2 + z_3 - 1} n^{i - z_0 - z_1}) \leq e^{-2^r \rho^{z_2 + z_3 - 1} n^{i - z_0 - z_1}} \leq e^{-\sqrt{n}}.
\]

Now, consider \( S' \in \mathcal{J}^n \). By the random choice of \( U_S \) and \( U_{S'} \), we have that
\[
\mathbb{P}(S' \in \mathcal{J}_{S,z,2}^b) = \mathbb{P}(b \setminus S' \subseteq U_{S'}, |U_{S'} \cap S| \geq z_3, |U_S \cap (S' \setminus b)| \geq 1) = \mathbb{P}(b \setminus S' \subseteq U_{S'}) \cdot \mathbb{P}(|U_{S'} \cap S| \geq z_3) \cdot \mathbb{P}(|U_S \cap (S' \setminus b)| \geq 1) \leq \rho^{z_2} \cdot \binom{i}{z_3} \rho^{z_3} \cdot (i - z_1 + 1) \rho \leq 2^{r+1} \rho^{z_2 + z_3}.
\]

However, note that the events \( S' \in \mathcal{J}_{S,z,2}^b \) and \( S'' \in \mathcal{J}_{S,z,2}^b \) are not necessarily independent. To deal with this, define the auxiliary \((i - z_0 - z_1 + 1)\)-graph \( A \) on \( V \) with edge set \( \{ S' \setminus (S \cup b) : S' \in \mathcal{J}^n \} \) and let \( A' \) be the (random) subgraph with edge set \( \{ S' \setminus (S \cup b) : S' \in \mathcal{J}_{S,z,2}^b \} \). Note that for every edge \( e \in A \), there are at most \( \binom{1}{z_3}(z_1 + z_2 - 1) \) \( \approx 2^r \rho \) elements \( S' \in \mathcal{J}^n \) with \( e = S' \setminus (S \cup b) \). Hence, \( |\mathcal{J}_{S,z,2}^b| \leq 2^{r+1} |A'| \). Moreover, every edge of \( A \) survives (i.e. lies in \( A' \)) with probability at
most $2^{2r} \cdot r^2 \rho^{2z+3} + 1$, and for every matching $M$ in $A$, the edges of $M$ survive independently. Thus, by Lemma 5.15, we have that
\[ \mathbb{P}(|A'| \geq 7r^2 \rho^{2z+3} + 1, n_i^{z_0-1} > 0, z_1 + 1) \leq (i - z_0 - z_1 + 1)n_i^{z_0-1} e^{-7r^2 \rho^{2z+3} + 1} \]
and thus
\[ \mathbb{P}(|A'| \geq 7r^2 \rho^{2z+3} + 1, n_i^{z_0-1} > 0, z_1 + 1) \leq r^n e^{-7r^2 \rho^{2z+3} + 1} \leq e^{-\sqrt{n}}. \]

Since $|S| \leq n^i$, a union bound applied to (10.1) and (10.2) shows that with probability at least $1 - e^{-n/3}$, (F3) holds.

The following ‘Localised cover down lemma’ allows us to simultaneously cover all $S$-important edges of an $i$-system $S$ provided that the associated focus $U$ satisfies (F1)–(F3) and all $S$-important edges are ‘localised’ in the sense that their links are contained in the respective focus set (or, equivalently, their type is maximal).

**Lemma 10.8 (Localised cover down lemma).** Let $1/n \ll \rho \ll \rho_{size}, \varepsilon, 1/f$ and $1 \leq i < r < f$. Assume that $(*)_{r-i}$ is true. Let $F$ be a weakly regular $r$-graph on $f$ vertices and $S^* \in \binom{V(F)}{i}$ such that $F(S^*)$ is non-empty. Let $G$ be a complex on $n$ vertices and let $S = \{S_1, \ldots, S_p\}$ be an $i$-system in $G$ such that $G$ is $r$-exclusive with respect to $S$. Let $U = \{U_1, \ldots, U_p\}$ be a $(\rho_{size}, \rho, r)$-focus for $S$. Suppose further that whenever $S_j \subseteq e \in G(r)$, we have $e \setminus S_j \subseteq U_j$. Finally, assume that $G(S_j)[U_j]$ is an $F(S^*)$-divisible $(\rho, \varepsilon, f - i, r - i)$-supercomplex for all $j \in [p]$.

Then there exists a $\rho^{-1/12}$-well separated $F$-packing $F$ in $G$ covering all $S$-important $r$-edges.

**Proof.** Recall that by Proposition 5.3, $F(S^*)$ is a weakly regular $(r - i)$-graph. We will use $(*)_{r-i}$ together with Corollary 4.15 in order to find many $F(S^*)$-decompositions of $G(S_j)[U_j]$ and then pick one of these at random. Let $t := \rho^{1/6}(0.5\rho_{size} n)^{r-1}$ and $\kappa := \rho^{-1/12}$. For all $j \in [p]$, define $G_j := G(S_j)[U_j]$. Consider Algorithm 10.9 which, if successful, outputs a $\kappa$-well separated $F(S^*)$-decomposition $F_j$ of $G_j$ for every $j \in [p]$.

**Algorithm 10.9**

```
for $j$ from 1 to $p$ do
    for all $z = (z_0, z_1, z_2, z_3) \in Z_{r,i}$, define $T_z^j$ as the $(z_1 + z_2)$-graph on $U_j$ containing all $Z_1 \cup Z_2 \subseteq U_j$ with $|Z_1| = z_1, |Z_2| = z_2$ such that for some $j' \in [j - 1]$ with $|S_j \cap S_{j'}| = z_0$ and some $K' \subseteq F_{j'}^{<f-1}$, we have $Z_1 \subseteq S_j', Z_3 \subseteq K'$ and $|K' \cap S_j| = z_3$
    if there exist $\kappa$-well separated $F(S^*)$-decompositions $F_{j,1}, \ldots, F_{j,t}$ of $G_j - \bigcup_{z \in Z_{r,i}} T_z^j$ which are pairwise $(f - i)$-disjoint then
        pick $s \in [t]$ uniformly at random and let $F_j := F_{j,s}$
    else
        return ‘unsuccessful’
end if
end for
```

**Claim 1:** If Algorithm 10.9 outputs $F_1, \ldots, F_p$, then $F := \bigcup_{j \in [p]} F_j$ is a packing as desired, where $\bar{F}_j := S_j \triangle F_j$.

**Proof of claim:** Since $z_1 + z_2 > r - i$, we have $G_j^{(r-i)} = (G_j - \bigcup_{z \in Z_{r,i}} T_z^j)^{(r-i)}$. Hence, $F_j$ is indeed an $F(S^*)$-decomposition of $G_j$. Thus, by Proposition 7.9, $\bar{F}_j$ is a $\kappa$-well separated $F$-packing in $G$ covering all $r$-edges containing $S_j$. Therefore, $F$ covers all $S$-important $r$-edges of $G$. By Fact 5.4(iii) it suffices to show that $\bar{F}_1, \ldots, \bar{F}_p$ are $r$-disjoint.

To this end, let $j' < j$ and suppose, for a contradiction, that there exist $K \in F_{j'}^{<f}$ and $K' \in F_{j'}^{<f}$ such that $|K \cap K'| \geq r$. Let $K := \bar{K} \cap S_j$ and $K' := \bar{K'} \cap S_j$. Then $F_j \subseteq F_{j'}^{<f-1}$ and $K' \in F_{j'}^{<f-1}$ and $(S_j \setminus K) \cap (S_{j'} \cup K') \geq r$. Let $z_0 := |S_j \setminus S_{j'}|$ and $z_3 := |S_j \cap K'|$. Hence, we have $|K \cap (S_{j'} \cup K')| \geq r - z_0 - z_3$. Choose $X \subseteq K$ such that $|X \cap (S_{j'} \cup K')| = r - z_0 - z_3.$
and let $Z_1 := X \cap S_j$ and $Z_2 := X \cap K'$. We claim that $z := (z_0, |Z_1|, |Z_2|, z_3) \in Z_{r,i}$. Clearly, we have $z_0 + |Z_1| + |Z_2| + z_3 = r$. Furthermore, note that $z_0 + z_3 < i$. Indeed, we clearly have $z_0 + z_3 = |S_j \cap (S_j' \cup K')| \leq |S_j| = i$, and equality can only hold if $S_j \subseteq S_j' \cup K' = K'$, which is impossible since $G$ is $r$-exclusive. Similarly, we have $z_0 + |Z_1| < i$. Thus, $z \in Z_{r,i}$. But this implies that $Z_1 \cup Z_2 \in T_i^2$, in contradiction to $Z_1 \cup Z_2 \subseteq K$.

In order to prove the lemma, it is thus sufficient to prove that with positive probability, $\Delta(T_i^2) \leq 2^{\rho f \cdot 1/2}|U_j|$ for all $j \in [p]$ and $z \in Z_{r,i}$. Indeed, this would imply that $\Delta(\bigcup_{z \in Z_{r,i}} T_i^2) \leq (r + 1)^{2^\omega} 2^{|U_j|}(\rho \cdot 1/2)|U_j|$ and by Proposition 5.9(v), $G_j - \bigcup_{z \in Z_{r,i}} T_i^2$ would be a $(\rho^{1/12}, \xi_j/2, f-i, r-i)-$supercomplex. By Corollary 4.15 and since $|U_j| \leq 0.5\rho p s_n n_i$, the number of pairwise $(f-i)$-disjoint $\kappa$-well separated $F(S')$-decompositions in $G_j - \bigcup_{z \in Z_{r,i}} T_i^2$ is at least $\rho^{1/12}|U_j|^{(f-i)-(r-i)} \geq t$, so the algorithm would succeed.

In order to analyse $\Delta(T_i^2)$, we define the following variables. Suppose that $1 \leq j' < j \leq p$, that $z = (z_0, z_1, z_2, z_3) \in Z_{r,i}$ and $b \subseteq U_j$ is a $(z_1 + z_2 - 1)$-set. Let $Y_{j,z}^{b,j'}$ denote the random indicator variable of the event that each of the following holds:

(a) there exists some $K' \in F_{j'}^{\leq (f-i)}$ with $|K' \cap S_j| = z_3$;
(b) there exist $Z_1 \subseteq S_j', Z_2 \subseteq K'$ with $|Z_1| = z_1$, $|Z_2| = z_2$ such that $b \subseteq Z_1 \cup Z_2 \subseteq U_j$;
(c) $|S_j \cap S_j'| = z_0$.

We say that $v \in \binom{U_j}{1}$ is a witness for $j'$ if (a)–(c) hold with $Z_1 \cup Z_2 = b \cup v$ and for all $j \in [p], z = (z_0, z_1, z_2, z_3) \in Z_{r,i}$ and $(z_1 + z_2 - 1)$-sets $b \subseteq U_j$, let $X^{b,j}_{j,z} := \sum_{j'=1}^{x^{b,j}_{j,z}} Y^{b,j}_{j,z}$.

Claim 2: For all $j \in [p], z = (z_0, z_1, z_2, z_3) \in Z_{r,i}$ and $(z_1 + z_2 - 1)$-sets $b \subseteq U_j$, we have $|T_i^2(b)| \leq 2^{\rho f \cdot kX^{b,j}_{j,z}}$.

Proof of claim: Let $j, z$ and $b$ be fixed. Clearly, if $v \in T_i^2(b)$, then by Algorithm 10.9, $v$ is a witness for some $j' \in [j - 1]$. Conversely, we claim that for each $j' \in [j - 1]$, there are at most $2^{\rho f \cdot k}$ witnesses for $j'$. Clearly, this would imply that $|T_i^2(b)| \leq 2^{\rho f \cdot k}|\{j' \in [j - 1] : \ Y^{b,j}_{j,z} = 1\}| = 2^{\rho f \cdot kX^{b,j}_{j,z}}$.

Fix $j' \in [j - 1]$. If $v$ is a witness for $j'$, then there exists $K_v \in F_j^{\leq (f-i)}$ such that (a)–(c) hold with $Z_1 \cup Z_2 = b \cup v$ and $K_v$ playing the role of $K'$. By (b) we must have $v \subseteq Z_1 \cup Z_2 \subseteq S_j' \cup K_v$. Since $|S_j' \cap K_v| = f$, there are at most $f$ witnesses $v'$ for $j'$ such that $K_v$ can play the role of $K_v$.

Note that for any possible choice of $Z_1, Z_2, K'$, we must have $|b \cap Z_2| \subseteq \{z_2, z_2 - 1\}$ and $b \cap Z_2 \subseteq Z_2 \subseteq K'$ by (b). For any $Z_2' \subseteq b$ with $|Z_2'| \subseteq \{z_2, z_2 - 1\}$ and any $Z_3 \in (S_j')$, there can be at most $\kappa K' \in F_j^{\leq (f-i)}$ with $Z_2' \subseteq K'$ and $K' \cap S_j = Z_3$. This is because $F_j^{\leq (f-i)}$ is a $\kappa$-well separated $F(S')$-decomposition and $|Z_2' \cup Z_3| \geq z_2 - 1 + z_3 \geq r - i$. Hence, there can be at most $2^{|Z_2'|} \leq 2^{\rho f \cdot k}$ possible choices for $K'$.

The following claim thus implies the lemma.

Claim 3: With positive probability, we have $X^{b,j}_{j,z} \leq \rho^{1/2}|U_j|$ for all $j \in [p], z = (z_0, z_1, z_2, z_3) \in Z_{r,i}$ and $(z_1 + z_2 - 1)$-sets $b \subseteq U_j$.

Proof of claim: Fix $j, z, b$ as above. We split $X^{b,j}_{j,z}$ into two sums. For this, let

$\mathcal{J}^{b,j}_{j,1} := \{j' \in [j - 1] : |S_j \cap S_j'| = z_0, b \setminus S_j' \subseteq U_j, |U_j \cap S_j| \geq z_3\},$

$\mathcal{J}^{b,j}_{j,2} := \{j' \in [j - 1] : b \cap S_j' = z_1\},$

$\mathcal{J}^{b,j}_{j,3} := \{j' \in [j - 1] : |U_j \cap (S_j' \setminus b)| \geq 1\}.$

Since $\mathcal{U}$ is a $(\rho_{size}, \rho, r)$-focus for $S$, (F3) implies that

\begin{align*}
|\mathcal{J}^{b,j}_{j,1}| &\leq 2^{\rho_{size} \cdot z_2 + z_3 - 1} n^i - z_0 - z_1, \\
|\mathcal{J}^{b,j}_{j,2}| &\leq 2^{\rho \cdot z_2 + z_3 + 1} n^i - z_0 - z_1 + 1.
\end{align*}
Note that if $Y_{j,z}^{b,j'} = 1$, then $j' \in \mathcal{J}_{j,z,1}^b \cup \mathcal{J}_{j,z,2}^b$. Hence, we have $X_{j,z}^b = X_{j,z,1}^b + X_{j,z,2}^b$, where $X_{j,z,1}^b := \sum_{j' \in \mathcal{J}_{j,z,1}^b} Y_{j,z}^{b,j'}$ and $X_{j,z,2}^b := \sum_{j' \in \mathcal{J}_{j,z,2}^b} Y_{j,z}^{b,j'}$. We will bound $X_{j,z,1}^b$ and $X_{j,z,2}^b$ separately.

For $j' \in \mathcal{J}_{j,z,1}^b \cup \mathcal{J}_{j,z,2}^b$, define

$$(10.5) \quad \mathcal{K}_{j,z}^{b,j'} := \{K' \in \binom{U_{j'}}{f_i} : b \subseteq S_j \cup K', \|K' \cap U_j\| \geq z_2, \|K' \cap S_j\| = z_3\}.$$ 

Note that if $Y_{j,z}^{b,j'} = 1$, then $F_{j',k}^{(f-i)} \cap \mathcal{K}_{j,z}^{b,j'} \neq \emptyset$. Recall that the candidates $F_{j',1}, \ldots, F_{j',t}$ in Algorithm 10.9 from which $F_{j'}$ was chosen at random are $(f-i)$-disjoint. We thus have

$$\mathbb{P}(Y_{j,z}^{b,j'} = 1) \leq \frac{\left|\{k \in [t] : F_{j',k}^{(f-i)} \cap \mathcal{K}_{j,z}^{b,j'} \neq \emptyset\}\right|}{t} \leq \frac{|\mathcal{K}_{j,z}^{b,j'}|}{t}.$$ 

This upper bound still holds if we condition on variables $Y_{j,z}^{b,j''}$, $j'' \neq j'$. We thus need to bound $|\mathcal{K}_{j,z}^{b,j'}|$ in order to bound $X_{j,z,1}^b$ and $X_{j,z,2}^b$.

**Step 1: Estimating $X_{j,z,1}^b$**

Consider $j' \in \mathcal{J}_{j,z,1}^b$. For all $K' \in \mathcal{K}_{j,z}^{b,j'}$, we have $b \subseteq S_j \subseteq K'$ and $|b \cap K'| = |b| - |b \cap S_j| = z_2 - 1$, and the sets $b \cap K'$, $K' \cap S_j$, $(K' \setminus b) \cap (U_j \cup U_{j'})$ are disjoint. Moreover, we have $|(K' \setminus b) \cap (U_j \cup U_{j'})| = |(K' \setminus b) \cap U_j| \geq |K' \cap U_j| - |b \cap K'| \geq 1$. We can thus count

$$|\mathcal{K}_{j,z}^{b,j'}| \leq \left[\binom{|S_j|}{z_3}\right] \cdot |U_j | \cdot |U_{j'}|^{f-i-(z_2-1)-1-z_3} \leq 2^i \cdot 2^2 \cdot 2^2 \cdot 2^{u_z} \cdot (2\rho \rho_{size} n)^{f-i-z_2-z_3}.$$ 

Let $\tilde{\rho}_1 := \rho^{z_0 + z_1 - i + 5/3} \rho_{size} n^{z_0 + z_1 - i} \in [0,1]$. In order to apply Proposition 5.11, let $j_1, \ldots, j_m$ be an enumeration of $\mathcal{J}_{j,z,1}^b$. We then have for all $k \in [m]$ and all $y_1, \ldots, y_{k-1} \in \{0,1\}$ that

$$\mathbb{P}(Y_{j,z}^{b,j_k} = 1 \mid Y_{j,z}^{b,j_1} = y_1, \ldots, Y_{j,z}^{b,j_{k-1}} = y_{k-1}) \leq \frac{|\mathcal{K}_{j,z}^{b,j_k}|}{t} \leq \frac{|\mathcal{K}_{j,z}^{b,j_k}|}{t} \leq \frac{\rho^{1/6}(2\rho \rho_{size} n)^{f-r}}{\rho^{1/6}(2\rho \rho_{size} n)^{f-r}} \leq \frac{2^{f-r+1-z_2-z_3} \rho^{1/6}(2\rho \rho_{size} n)^{z_0 + z_1 - i} \rho_{size} n^{z_0 + z_1 - i}}{\rho^{1/6}(2\rho \rho_{size} n)^{z_0 + z_1 - i} \rho_{size} n^{z_0 + z_1 - i}} \leq \tilde{\rho}_1.$$ 

Let $B_1 \sim \text{Bin}(|\mathcal{J}_{j,z,1}^b|, \tilde{\rho}_1)$ and observe that

$$\mathbb{P}(X_{j,z,1}^b \geq 0.5 \rho^{1/2}|U_j|) \leq \mathbb{P}(B_1 \geq 0.5 \rho^{1/2}|U_j|) \leq e^{-0.5 \rho^{1/2}|U_j|}.$$ 

**Step 2: Estimating $X_{j,z,2}^b$**

Consider $j' \in \mathcal{J}_{j,z,2}^b$. This time, since $|b \cap S_j| = z_1 - 1$, we have $|K' \cap b| = |b \setminus S_j| = z_2$ for all $K' \in \mathcal{K}_{j,z}^{b,j'}$. Thus, we count

$$|\mathcal{K}_{j,z}^{b,j'}| \leq \left[\binom{|S_j|}{z_3}\right] \cdot |U_{j'}|^{f-i-z_2-z_3} \leq 2^i \cdot (2\rho \rho_{size} n)^{f-i-z_2-z_3}.$$ 

Let $\tilde{\rho}_2 := \rho^{z_0 + z_1 - i + 1/3} \rho_{size} n^{z_0 + z_1 - i} \in [0,1]$. In order to apply Proposition 5.11, let $j_1, \ldots, j_m$ be an enumeration of $\mathcal{J}_{j,z,2}^b$. We then have for all $k \in [m]$ and all $y_1, \ldots, y_{k-1} \in \{0,1\}$ that

$$\mathbb{P}(Y_{j,z}^{b,j_k} = 1 \mid Y_{j,z}^{b,j_1} = y_1, \ldots, Y_{j,z}^{b,j_{k-1}} = y_{k-1}) \leq \frac{|\mathcal{K}_{j,z}^{b,j_k}|}{t} \leq \frac{\rho^{1/6}(2\rho \rho_{size} n)^{f-r}}{\rho^{1/6}(2\rho \rho_{size} n)^{f-r}} \leq \frac{2^{f-r-2-z_2} \rho^{1/6}(2\rho \rho_{size} n)^{z_0 + z_1 - i}}{\rho^{1/6}(2\rho \rho_{size} n)^{z_0 + z_1 - i}} \leq \tilde{\rho}_2.$$
Let $B_2 \sim \text{Bin}(|J_{x,z}|, \tilde{\rho}_2)$ and observe that
\[
7\mathbb{E}B_2 = 7|J_{x,z}| \tilde{\rho}_2 \overset{(10.4)}{=} 7 \cdot 2^{9r} \rho \cdot 2^{z+i} 2^{-i} - 1/5 \rho_{\text{size}} n - 2^{z+i} - 1/5 \rho_{\text{size}} n \leq 0.5\rho^{1/2}|U_j|.
\]
Thus,
\[
\mathbb{P}(X_{x,z} \geq 0.5\rho^{1/2}|U_j|) \leq \mathbb{P}(B_2 \geq 0.5\rho^{1/2}|U_j|) \leq e^{-0.5\rho^{1/2}|U_j|}.
\]
Hence,
\[
\mathbb{P}(X_{x,z} \geq \rho^{1/2}|U_j|) \leq \mathbb{P}(X_{x,z} \geq 0.5\rho^{1/2}|U_j|) + \mathbb{P}(X_{x,z} \geq 0.5\rho^{1/2}|U_j|) \leq 2e^{-0.5\rho^{1/2}|U_j|}.
\]
Since $p = |S| \leq n^t$, a union bound easily implies Claim 3.

This completes the proof of Lemma 10.8. \(\square\)

10.2. Partition pairs. We now develop the appropriate framework to be able to state the Cover down lemma for setups (Lemma 10.24). Recall that we will consider (and cover) $r$-sets separately according to their type. The type of an $r$-set $e$ naturally imposes constraints on the type of an $f$-set which covers $e$. We will need to track and adjust the densities of $r$-sets with respect to $f$-sets for each pair of types separately. This gives rise to the following concepts of partition pairs and partition regularity (see Section 10.3). We will sometimes refer to $r$-sets as ‘edges’ and to $f$-sets as ‘cliques’.

Let $X$ be a set. We say that $P = (X_1, \ldots, X_n)$ is an ordered partition of $X$ if the $X_i$ are disjoint subsets of $X$ whose union is $X$. We let $P(i) := X_i$ and $P([i]) := (X_1, \ldots, X_i)$. If $P = (X_1, \ldots, X_n)$ is an ordered partition of $X$, and $X' \subseteq X$, we let $P[X']$ denote the ordered partition $(X_1 \cap X', \ldots, X_n \cap X')$ of $X'$. If $(X', X'')$ is a partition of $X$, $P' = (X_1', \ldots, X_n')$ is an ordered partition of $X'$ and $P'' = (X_1'', \ldots, X_n'')$ is an ordered partition of $X''$, we let
\[
P' \sqcup P'' := (X_1', \ldots, X_a', X_a'', \ldots, X_n'').
\]

Definition 10.10. Let $G$ be a complex and let $f > r \geq 1$. An $(r, f)$-partition pair of $G$ is a pair $(P_r, P_f)$, where $P_r$ is an ordered partition of $G^{(r)}$ and $P_f$ is an ordered partition of $G^{(f)}$, such that for all $E \in P_r$ and $Q \in P_f$, every $Q \in Q$ contains the same number $C(E, Q)$ of elements from $E$. We call $C: P_r \times P_f \rightarrow \binom{|f|}{0}$ the containment function of the partition pair. We say that $(P_r, P_f)$ is upper-triangular if $C(P_r(i), P_f(k)) = 0$ whenever $f > k$.

Clearly, for every $Q \in P_f$, $\sum_{E \in P_r} C(E, Q) = \binom{|f|}{0}$. If $(P_r, P_f)$ is an $(r, f)$-partition pair of $G$ and $G' \subseteq G$ is a subcomplex, we define
\[
(P_r, P_f)[G'] := (P_r|G^{(r)}], P_f|G^{(f)}]).
\]

Clearly, $(P_r, P_f)[G']$ is an $(r, f)$-partition pair of $G'$.

Example 10.11. Suppose that $G$ is a complex and $U \subseteq V(G)$. For $\ell \in \mathbb{N}_0$, define $\mathcal{E}_\ell := \{e \in G^{(r)} : |e \cap U| = \ell\}$. For $k \in |f|_0$, define $\mathcal{Q}_k := \{Q \in G^{(f)} : |Q \cap U| = k\}$. Let $P_r := (\mathcal{E}_0, \ldots, \mathcal{E}_f)$ and $P_f := (\mathcal{Q}_0, \ldots, \mathcal{Q}_f)$. Then clearly $(P_r, P_f)$ is an $(r, f)$-partition pair of $G$, where the containment function is given by $C(\mathcal{E}_\ell, \mathcal{Q}_k) = \binom{|f|}{0}(f - k - 1, \ell)$. In particular, $C(\mathcal{E}_\ell, \mathcal{Q}_k) = 0$ whenever $\ell > k$ or $k > f - r + 1$. We say that $(P_r, P_f)$ is the $(r, f)$-partition pair of $G$, $U$.

The partition pairs we use are generalisations of the above example. More precisely, suppose that $G$ is a complex, $\mathcal{S}$ is an $i$-system in $V(G)$ and $\mathcal{U}$ is a focus for $\mathcal{S}$. Moreover, assume that $G$ is $r$-exclusive with respect to $\mathcal{S}$. For $r' \geq r$, let $\tau_{r'}$ denote the type function of $G^{(r')}$, $\mathcal{S}, \mathcal{U}$. As in the above example, if $\mathcal{E}_\ell := \tau_{r'}^{-1}(\ell)$ for all $\ell \in [r - i]|_0$ and $\mathcal{Q}_k := \tau_{r'}^{-1}(k)$ for all $k \in [f - i]|_0$, then every $Q \in \mathcal{Q}_k$ contains exactly $\binom{|f|}{0}(f - k - 1, \ell)$ elements from $\mathcal{E}_\ell$. However, we also have to consider $\mathcal{S}$-unimportant edges and cliques. It turns out that it is useful to assume that the unimportant edges and cliques are partitioned into $i$ parts each, in an upper-triangular fashion.
$\begin{array}{|c|c|c|c|c|c|c|c|}
\hline
\mathcal{P}_r^i(1) & \ldots & \mathcal{P}_r^i(i) & \tau_r^{-1}(0) & \tau_r^{-1}(1) & \ldots & \tau_r^{-1}(f-r) & \ldots & \tau_r^{-1}(f-i) \\
\hline
\mathcal{P}_r^i(1) & * & & & & & & & \\
\hline
\vdots & 0 & * & & & & & & \\
\hline
\tau_r^{-1}(0) & 0 & 0 & * & & & & & \\
\hline
\vdots & 0 & 0 & 0 & * & & & & \\
\hline
\tau_r^{-1}(r-i) & 0 & 0 & 0 & 0 & 0 & * & & \\
\hline
\end{array}
$

Figure 1. The above table sketches the containment function of an $(r, f)$-partition pair induced by $(\mathcal{P}_r^i, \mathcal{P}_f^j)$ and $\mathcal{U}$. The cells marked with * and the shaded subtable will play an important role later on.

More formally, for $r' \geq r$, let $\mathcal{D}_{r'}$ denote the set of $S$-unimportant $r'$-sets of $G$ and assume that $\mathcal{P}_r^i$ is an ordered partition of $\mathcal{D}_r$ and $\mathcal{P}_f^j$ is an ordered partition of $\mathcal{D}_f$. We say that $(\mathcal{P}_r^i, \mathcal{P}_f^j)$ is admissible with respect to $G, S, \mathcal{U}$ if the following hold:

(P1) $|\mathcal{P}_r^i| = |\mathcal{P}_f^j| = i$;
(P2) for all $S \in S, h \in [r-i]_0$ and $B \subseteq G(S)^{(h)}$ with $1 \leq |B| \leq 2^h$ and all $\ell \in [i]$, there exists $D(S, B, \ell) \in \mathbb{N}_0$ such that for all $Q \in \bigcap_{b \in B} G(S \cup b)[U_S]^{(f-i-h)}$, we have that

$$\{e \in \mathcal{P}_r^i(\ell) : \exists b \in B : e \subseteq S \cup b \cup Q\} = D(S, B, \ell);$$

(P3) $(\mathcal{P}_r^i \cup \{G(r) \setminus \mathcal{D}_r\}, \mathcal{P}_f^j \cup \{G(f) \setminus \mathcal{D}_f\})$ is an upper-triangular $(r, f)$-partition pair of $G$.

Note that for $i = 0$, $S = \{\emptyset\}$ and $\mathcal{U} = \{U\}$ for some $U \subseteq V(G)$, the pair $(\emptyset, \emptyset)$ trivially satisfies these conditions. Also note that (P2) can be viewed as an analogue of the containment function (from Definition 10.10) which is suitable for dealing with supercomplexes.

Assume that $(\mathcal{P}_r^i, \mathcal{P}_f^j)$ is admissible with respect to $G, S, \mathcal{U}$. Define

$$\mathcal{P}_r := \mathcal{P}_r^i \cup \{\tau_r^{-1}(0), \ldots, \tau_r^{-1}(r-i)\},$$

$$\mathcal{P}_f := \mathcal{P}_f^j \cup \{\tau_f^{-1}(0), \ldots, \tau_f^{-1}(f-i)\}.$$ 

It is not too hard to see that $(\mathcal{P}_r, \mathcal{P}_f)$ is an $(r, f)$-partition pair of $G$. Indeed, $\mathcal{P}_r$ clearly is a partition of $G^{(r)}$ and $\mathcal{P}_f$ is a partition of $G^{(f)}$. Suppose that $C$ is the containment function of $(\mathcal{P}_r^i \cup \{G(r) \setminus \mathcal{D}_r\}, \mathcal{P}_f^j \cup \{G(f) \setminus \mathcal{D}_f\})$. Then $C'$ as defined below is the containment function of $(\mathcal{P}_r, \mathcal{P}_f)$:

- For all $E \in \mathcal{P}_r^i$ and $Q \in \mathcal{P}_f^j$, let $C'(E, Q) := C(E, Q)$.
- For all $\ell \in [r-i]_0$ and $Q \in \mathcal{P}_f^j$, let $C'(\tau_r^{-1}(\ell), Q) := 0$.
- For all $E \in \mathcal{P}_r^i$ and $k \in [f-i]_0$, define $C'(E, \tau_f^{-1}(k)) := C(E, \{G(f) \setminus \mathcal{D}_f\})$.
- For all $\ell \in [r-i]_0$, $k \in [f-i]_0$, let

$$C'(\tau_r^{-1}(\ell), \tau_f^{-1}(k)) := \binom{k}{\ell} \frac{(f-i-k)}{(r-i-\ell)}.$$ 

We say that $(\mathcal{P}_r, \mathcal{P}_f)$ as defined above is induced by $(\mathcal{P}_r^i, \mathcal{P}_f^j)$ and $\mathcal{U}$.

Finally, we say that $(\mathcal{P}_r, \mathcal{P}_f)$ is an $(r, f)$-partition pair of $G, S, \mathcal{U}$, if

- $(\mathcal{P}_r([i]), \mathcal{P}_f([i]))$ is admissible with respect to $G, S, \mathcal{U}$;
- $(\mathcal{P}_r, \mathcal{P}_f)$ is induced by $(\mathcal{P}_r([i]), \mathcal{P}_f([i]))$ and $\mathcal{U}$.

The next proposition summarises basic properties of an $(r, f)$-partition pair of $G, S, \mathcal{U}$.

**Proposition 10.12.** Let $0 \leq i < r < f$ and suppose that $G$ is a complex, $S$ is an $i$-system in $V(G)$ and $\mathcal{U}$ is a focus for $S$. Moreover, assume that $G$ is $r$-exclusive with respect to $S$. Let $(\mathcal{P}_r, \mathcal{P}_f)$ be an $(r, f)$-partition pair of $G, S, \mathcal{U}$ with containment function $C$. Then the following hold:

(P1') $|\mathcal{P}_r| = r + 1$ and $|\mathcal{P}_f| = f + 1$;

(P2') for $i \leq \ell < r + 1$, $\mathcal{P}_r(\ell) = \tau_r^{-1}(\ell - i - 1)$, and for $i < k \leq f + 1$, $\mathcal{P}_f(k) = \tau_f^{-1}(k - i - 1)$;
In other words, $\ell$ for all $\ell \in [r+1]$, with $P_r$ playing the role of $P_r^*$.

(P6') if $i = 0$, $S = \{\emptyset\}$ and $U = \{U\}$ for some $U \subseteq V(G)$, then the (unique) $(r, f)$-partition pair of $G$, $S, U$ is the $(r, f)$-partition pair of $G$, $U$ (cf. Example 10.11);

(P7') for every subcomplex $G' \subseteq G$, $(P_r, P_f)[G']$ is an $(r, f)$-partition pair of $G'$, $S, U$.

**Proof.** Clearly, (P1'), (P2') and (P6') hold, and it is also straightforward to check (P7'). Moreover, (P3') holds because of (P3) and (10.6). The latter also implies (P4').

Finally, consider (P5'). For $\ell \in [i]$, this holds since $(P_r([i]), P_f([i]))$ is admissible, so assume that $\ell > i$. We have $P_r(\ell) = \tau^{-1}_r(\ell - i - 1)$. Let $S \in S$, $h \in [r - i_0]$ and $B \subseteq G(S)^h$ with $1 \leq |B| \leq 2^{h}$.

For $Q \in \bigcap_{b \in B} G(S \cup b)[U_S]^{(j-i-h)}$, let $D_Q := \{e \in G^{(r)} : S \subseteq e, |e \cap U_S| = \ell - i - 1, \exists b \in B : e \setminus S \subseteq b \cup Q\}$.

It is easy to see that
$$\{e \in P_r(\ell) : \exists b \in B : e \subseteq S \cup b \cup Q\} = D_Q.$$ Note that for every $e \in D_Q$, we have $e = S \cup (\bigcup B \cap e \cup (Q \cap e)$. It remains to show that for all $Q, Q' \in \bigcap_{b \in B} G(S \cup b)[U_S]^{(j-i-h)}$, we have $|D_Q| = |D_Q'|$. Let $\pi : Q \to Q'$ be any bijection. For each $e \in D_Q$, define $\pi'(e) := S \cup (\bigcup B \cap e \cup (Q \cap e)$. It is straightforward to check that $\pi' : D_Q \to D_Q'$ is a bijection. \hfill \Box

### 10.3. Partition regularity.

**Definition 10.13.** Let $G$ be a complex on $n$ vertices and $(P_r, P_f)$ an $(r, f)$-partition pair of $G$ with $a := |P_r|$ and $b := |P_f|$. We say that $G$ is $(\varepsilon, A, f, r)$-regular with respect to $(P_r, P_f)$ if for all $\ell \in [a]$, $k \in [b]$ and $e \in P_r(\ell)$, we have

$$(10.7) \quad |(P_f(k))(e)| = (a_{\ell,k} \pm \varepsilon)n^{f,r},$$

where we view $P_f(k)$ as a subgraph of $G^{(r)}$. If $E \subseteq P_r(\ell)$ and $Q \subseteq P_f(k)$, we will often write $A(\varepsilon, Q)$ instead of $a_{\ell,k}$.

For $A \in [0,1]^{a \times b}$ with $1 \leq t \leq a \leq b$, we define

- $\min^{\downarrow}(A) := \min\{a_{j,t} : j \in [a]\}$ as the minimum value on the diagonal,
- $\min^{\downarrow}(A) := \min\{a_{j,b-a} : j \in [a-t+1, \ldots, a]\}$
- $\min^{\uparrow}(A) := \min\{\min^{\downarrow}(A), \min^{\downarrow}(A)\}$.

Note that $\min^{\downarrow}(A)$ is the minimum value of the entries in $A$ that correspond to the entries marked with $\star$ in Figure 1.

**Example 10.14.** Suppose that $G$ is a complex and that $U \subseteq V(G)$ is $(\varepsilon, \mu, \xi, f, r)$-random in $G$ (see Definition 7.1). Let $(P_r, P_f)$ be the $(r, f)$-partition pair of $G$, $U$ (cf. Example 10.11). Let $Y \subseteq G^{(f)}$ and $d \geq \xi$ be such that (R2) holds. Define the matrix $A \in [0,1]^{(r+1) \times (f+1)}$ as follows: for all $\ell \in [r+1]$ and $k \in [f+1]$, let

$$a_{\ell,k} := \binom{f-r,\mu,k-\ell}{d}.$$

For all $\ell \in [r+1]$, $k \in [f+1]$ and $e \in P_r(\ell)$, we have that

$$\text{bin}(f-r,\mu,k-\ell)d.$$
In the proof of the Cover down lemma for setups, we face (amongst others) the following two challenges: (i) given an \((\varepsilon,A,f,r)\)-regular complex \(G\) for some suitable \(A\), we need to find an efficient \(F\)-packing in \(G\); (ii) if \(A\) is not suitable for (i), we need to find a ‘representative’ subcomplex \(G’\) of \(G\) which is \((\varepsilon,A’,f,r)\)-regular for some \(A’\) that is suitable for (i). The strategy to implement (i) is similar to that of the Boost lemma (Lemma 6.3): We randomly sparsify \(G(f)\) according to a suitably chosen (non-uniform) probability distribution in order to find \(Y^* \subseteq G(f)\) such that \(G[Y^*]\) is \((\varepsilon,d,f,r)\)-regular. We can then apply the Boosted nibble lemma (Lemma 6.4). The desired probability distribution arises from a non-negative solution to the equation \(Ax = \mathbb{1}\). The following condition on \(A\) allows us to find such a solution (cf. Proposition 10.16).

**Definition 10.15.** We say that \(A \in [0,1]^{a \times b}\) is diagonal-dominant if \(a_{k,k} \leq a_{k,k}/2(a-k)\) for all \(1 \leq k < k \leq \min\{a,b\}\).

**Proposition 10.16.** Let \(A \in [0,1]^{a \times b}\) be upper-triangular and diagonal-dominant with \(a \leq b\). Then there exists \(x \in [0,1]^b\) such that \(x \geq \min\\{A\}/4b\) and \(Ax = \min\\{A\}\mathbb{1}\).

**Proof.** If \(\min\\{A\} = 0\), we can take \(x = 0\), so assume that \(\min\\{A\} > 0\). For \(k > a\), let \(y_k := 1/4b\). For \(k\) from \(a\) down to \(1\), let \(y_k := a_{k,1}^{-1}(1 - \sum_{j=k+1}^{b} a_{j,j}y_j)\). Since \(A\) is upper-triangular, we have \(Ay = \mathbb{1}\). We claim that \(1/4b \leq y_k \leq a_{k,k}^{-1}\) for all \(k \in [b]\). This clearly holds for all \(k > a\). Suppose that for some \(k \in [a]\), we have already checked that \(1/4b \leq y_j \leq a_{j,j}^{-1}\) for all \(j > k\). We now check that

\[
1 \geq 1 - \sum_{j=k+1}^{b} a_{j,j}y_j \geq 1 - \sum_{j=k+1}^{a} \frac{a_{j,j}}{2(a-k)}y_j - \frac{b-a}{4b} \geq \frac{3}{4} - \frac{a-k}{2(a-k)} = \frac{1}{4}
\]

and so \(1/4b \leq y_k \leq a_{k,k}^{-1}\). Thus we can take \(x := \min\\{A\}y\). \(\square\)

**Lemma 10.17.** Let \(1/n \ll \varepsilon \ll \xi, 1/f\) and \(r \in [f-1]\). Suppose that \(G\) is a complex on \(n\) vertices and \((P_r,P_f)\) is an upper-triangular \((r,f)\)-partition pair of \(G\) with \(|P_r| \leq |P_f| \leq f + 1\). Let \(A \in [0,1]|P_r| \times |P_f|\) be diagonal-dominant with \(d := \min\\{A\} \geq \xi\). Suppose that \(G\) is \((\varepsilon,A,f,r)\)-regular with respect to \((P_r,P_f)\) and \((\xi,f+r,r)\)-dense. Then there exists \(Y^* \subseteq G(f)\) such that \(G[Y^*]\) is \((2f\varepsilon,d,f,r)\)-regular and \((0.9\xi((f+1))^{(f+r)},f+r,r)\)-dense.

**Proof.** Since \((P_r,P_f)\) is upper-triangular, we may assume that \(A\) is upper-triangular too. By Proposition 10.16, there exists a vector \(x \in [0,1]|P_f|\) with \(x \geq \min\\{A\}/4(f+1) \geq \xi/4(f+1)\) and \(Ax = d\mathbb{1}\).

Obtain \(Y^* \subseteq G(f)\) randomly by including every \(Q \in G(f)\) that belongs to \(P_f(k)\) with probability \(x_k\), all independently. Let \(e \in P_r(\ell)\) for any \(\ell \in |P_r|\). We have

\[
\mathbb{E}[G[Y^*]^{(f)}(e)] = \sum_{k=1}^{|P_f|} x_k(a_{\ell,k} \pm \varepsilon)n^{f-r} = (d \pm (f+1)\varepsilon)n^{f-r}.
\]

Then, combining Lemma 5.10(ii) with a union bound, we conclude that whp \(G[Y^*]\) is \((2f\varepsilon,d,f,r)\)-regular.

Let \(e \in G(r)\). Since \(|G^{(f+r)}(e)| \geq \xi n^f\) and every \(Q \in G^{(f+r)}(e)\) belongs to \(G[Y^*]^{(f+r)}(e)\) with probability at least \((\xi/4(f+1))^{(f+r)}\), we conclude with Corollary 5.14 that with probability at least \(1 - e^{-n/6}\), we have

\[
|G[Y^*]^{(f+r)}(e)| \geq 0.9(\xi/4(f+1))^{(f+r)}|G^{(f+r)}(e)| \geq 0.9\xi(\xi/4(f+1))^{(f+r)}n^f.
\]

Applying a union bound shows that whp \(G[Y^*]\) is \((0.9\xi((f+1))^{(f+r)},f+r,r)\)-dense. \(\square\)
The following concept of a setup turns out to be the appropriate generalisation of Definition 7.1 to $i$-systems and partition pairs.

**Definition 10.18 (Setup).** Let $G$ be a complex on $n$ vertices and $0 \leq i < r < f$. We say that $\mathcal{S}, \mathcal{U}, (P_r, P_f)$ form an $(\varepsilon, \mu, \xi, f, r, i)$-setup for $G$ if there exists an $f$-graph $Y$ on $V(G)$ such that the following hold:

1. ($S1$) $\mathcal{S}$ is an $i$-system in $V(G)$ such that $G$ is $r$-exclusive with respect to $\mathcal{S}$; $\mathcal{U}$ is a $\mu$-focus for $\mathcal{S}$ and $(P_r, P_f)$ is an $(r, f)$-partition pair of $G$, $\mathcal{S}$, $\mathcal{U}$;
2. ($S2$) there exists a matrix $A \in [0,1])^{(r+1)\times(f+1)}$ with $\min\{r-i+1\} \geq \xi$ such that $G[Y]$ is $(\varepsilon, A, f, r)$-regular with respect to $(P_r, P_f)$.
3. ($S3$) every $\mathcal{S}$-unimportant $e \in G^{(r)}$ is contained in at least $\xi(\mu n)^f$ $\mathcal{S}$-unimportant $Q \in G[Y]^{(f+r)}$ and for every $\mathcal{S}$-important $e \in G^{(r)}$ with $e \geq S \in \mathcal{S}$, we have $\|G[Y]^{(f+r)}(e)[U_S]\| \geq \xi(\mu n)^f$;
4. ($S4$) for all $S \in \mathcal{S}$, $h \in [r-i]_0$ and all $B \subseteq G(S)^{(h)}$ with $1 \leq |B| \leq 2^h$ we have that $\bigcap_{b \in B} G(S \cup b)[U_S]$ is an $(\varepsilon, \xi, f-i-h, r-i-h)$-complex.

Moreover, if ($S1$)–($S4$) are true and $A$ is diagonal-dominant, then we say that $\mathcal{S}, \mathcal{U}, (P_r, P_f)$ form a diagonal-dominant $(\varepsilon, \mu, \xi, f, r, i)$-setup for $G$.

Note that ($S4$) implies that $G(S)[U_S]$ is an $(\varepsilon, \xi, f-i, r-i)$-supercomplex for every $S \in \mathcal{S}$, but is stronger in the sense that $B$ is not restricted to $U_S$. The following observation shows that Definition 10.18 does indeed generalise Definition 7.1. (Recall that the partition pair of $G, U$ was defined in Example 10.11.) We will use it to derive the Cover down lemma from the more general Cover down lemma for setups.

**Proposition 10.19.** Let $G$ be a complex on $n$ vertices and suppose that $U \subseteq V(G)$ is $(\varepsilon, \mu, \xi, f, r)$-random in $G$. Let $(P_r, P_f)$ be the $(r, f)$-partition pair of $G, U$. Then $\{\emptyset\}, \{U\}, (P_r, P_f)$ form an $(\varepsilon, \mu, \xi, f, r)$-setup for $G$, where $\mu := (\min\{\mu, 1 - \mu\})^{r-f}$.

**Proof.** We first check ($S1$). Clearly, $\mathcal{S}$ is a 0-system in $V(G)$. Moreover, $G$ is trivially $r$-exclusive with respect to $\mathcal{S}$ since $|\mathcal{S}| < 2$. Moreover, by ($R1$), $\mathcal{U}$ is a $\mu$-focus for $\mathcal{S}$, and $(P_r, P_f)$ is an $(r, f)$-partition pair of $G$, $\mathcal{S}$, $\mathcal{U}$ by ($P6'$) in Proposition 10.12. Note that ($S4$) follows immediately from ($R4$). In order to check ($S2$) and ($S3$), assume that $Y \subseteq G^{(f)}$ and $\xi \geq \xi$ are such that ($R2$) and ($R3$) hold. Clearly, all $e \in G^{(r)}$ are $\mathcal{S}$-important, and by ($R3$), we have for all $e \in G^{(r)}$ that $\|G[Y]^{(f+r)}(e)[U]\| \geq \xi(\mu n)^f$, so ($S3$) holds. Finally, we have seen in Example 10.14 that there exists a matrix $A \in [0,1]^{(r+1)\times(f+1)}$ with $\min\{r-i+1\} \geq \mu \xi$ such that $G[Y]$ is $(\varepsilon, A, f, r)$-regular with respect to $(P_r, P_f)[Y]$. $\square$

The following lemma shows that we can (probabilistically) sparsify a given setup so that the resulting setup is diagonal-dominant.

**Lemma 10.20.** Let $1/n \leq \varepsilon \leq \nu \leq \mu, \xi, f/r$ and $0 \leq i < r < f$. Let $\varepsilon' := \nu^{\varepsilon-1/2}$. Let $G$ be a complex on $n$ vertices and suppose that $\mathcal{S}, \mathcal{U}, (P_r, P_f)$ form an $(\varepsilon, \mu, \xi, f, r, i)$-setup for $G$.

Then there exists a subgraph $H \subseteq G^{(r)}$ with $\Delta(H) \leq 1.1vn$ and the following property: for all $L \subseteq G^{(r)}$ with $\Delta(L) \leq \varepsilon n$ and all $(r+1)$-graphs $O$ on $V(G)$ with $\Delta(O) \leq \varepsilon n$, the following holds for $G' := G[H \triangle L] - O$:

$\mathcal{S}, \mathcal{U}, (P_r, P_f)[G']$ form a diagonal-dominant $(\sqrt{\varepsilon}, \mu, \xi', f, r, i)$-setup for $G'$.

**Proof.** Let $Y \subseteq G^{(f)}$ and $A \in [0,1]^{(r+1)\times(f+1)}$ be such that ($S1$)–($S4$) hold for $G$. Let $C: P_r \times P_f \to [f]_0$ be the containment function of $(P_r, P_f)$. We will write $c_{\ell,k} := C(P_r(\ell), P_f(k))$ for all $\ell \in [r+1]$ and $k \in [f+1]$. We may assume that $a_{\ell,k} = 0$ whenever $c_{\ell,k} = 0$ (and $\min\{r-i+1\} \geq \xi$ still holds).

Define the matrix $A' \in [0,1]^{(r+1)\times(f+1)}$ by letting $a'_{\ell,k} := a_{\ell,k} \nu^{-\ell} \prod_{\ell' \in [r+1]} \nu^{\ell'c_{\ell',k}}$. Note that we always have $a'_{\ell,k} \leq a_{\ell,k}$.

**Claim 1:** $A'$ is diagonal-dominant and $\min\{r-i+1\} \geq \xi'$. 

Proof of claim: For $1 \leq \ell < k \leq r + 1$, 
\[
\frac{a_{\ell,k}}{a_{r,k}} = \frac{\nu_{r-k}}{\nu_{r-k}} \leq \left(\frac{k-1}{\xi} \right) \leq \frac{1}{2(r+1-\ell)}. 
\]
Moreover, we have \(\min_{\ell \in [r+1]} \xi \geq \xi'\).

We choose $H$ randomly by including independently each $e \in \mathcal{P}_r(\ell)$ with probability $\nu', \forall \ell \in [r+1]$. A standard application of Lemma 5.10 shows that \(\text{whp} \Delta(H) \leq 1.1n\).

We now check (S1)–(S4) for $G', \mathcal{S}, \mathcal{U}$, and $(\mathcal{P}_r, \mathcal{P}_f)[G']$. For any $L$ and $O$, $G'$ is $r$-exclusive with respect to $\mathcal{S}$, and $(\mathcal{P}_r, \mathcal{P}_f)[G']$ is an $(r, f)$-partition pair of $G'$, $\mathcal{S}, \mathcal{U}$ by $(P'')$ in Proposition 10.12. Thus, (S1) holds.

We now consider (S2). Let $\ell \in [r+1]$, $k \in [f+1]$ and $e \in \mathcal{P}_r(\ell)$. Define
\[
\mathcal{Q}_{e,k} := (\mathcal{P}_f[Y](k))(e).
\]
By (10.7) and (S2) for $\mathcal{S}, \mathcal{U}, (\mathcal{P}_r, \mathcal{P}_f)$, we have that $|\mathcal{Q}_{e,k}| = (a_{\ell,k} \pm \varepsilon)n^{f-r}$. We view $\mathcal{Q}_{e,k}$ as a $(f-r)$-graph and consider the random subgraph $\mathcal{Q}'_{e,k}$ that contains all $Q \in \mathcal{Q}_{e,k}$ with $(\mathcal{Q}'_{e,k}) \setminus \{e\} \subseteq H$. If $a_{\ell,k} \neq 0$, then for all $Q \in \mathcal{Q}_{e,k}$, we have
\[
\mathbb{P}(Q \in \mathcal{Q}'_{e,k}) = \nu^{-\ell} \prod_{e' \in [r+1]} \nu^{\ell_{e',k}} = \frac{a_{\ell,k}}{a_{\ell,k}}.
\]
Thus, $\mathbb{E}|\mathcal{Q}'_{e,k}| = (a_{\ell,k} \pm \varepsilon)n^{f-r}$. This also holds if $a_{\ell,k} = 0$ (and thus $a_{\ell,k} = 0$). Using Corollary 5.14 and a union bound, we thus conclude that with probability at least $1 - e^{-n^{1/7}}$, we have $|\mathcal{Q}'_{e,k}| = (a_{\ell,k} \pm \varepsilon^{2/3})n^{f-r}$ for all $\ell \in [r+1]$, $k \in [f+1]$ and $e \in \mathcal{P}_r(\ell)$. (Technically, we can only apply Corollary 5.14 if $|\mathcal{Q}_{e,k}| \geq 2\varepsilon n^{f-r}$, say. Note that the result holds trivially if $|\mathcal{Q}_{e,k}| \leq 2\varepsilon n^{f-r}$.) Assuming that this holds for $H$, a double application of Proposition 5.7 shows that any $L \subseteq G^{(r)}$ with $\Delta(L) \leq \varepsilon n$ and any $(r+1)$-graph $O$ on $V(G)$ with $\Delta(O) \leq \varepsilon n$ results in $G'[Y]$ being $(\sqrt{\varepsilon}, A', f, r)$-regular with respect to $(\mathcal{P}_r, \mathcal{P}_f)[G'[Y]]$.

We now check (S3). If $e$ is $\mathcal{S}$-unimportant then let $\mathcal{Q}_{e}$ be the set of all $Q \in G'[Y]^{(f+r)}(e)$ such that $Q \cup e$ is $\mathcal{S}$-unimportant, otherwise let $\mathcal{Q}_{e} := G'[Y]^{(f+r)}(e)[U_S]$. By (S3) for $\mathcal{S}, \mathcal{U}, (\mathcal{P}_r, \mathcal{P}_f)$, we have that $|\mathcal{Q}_{e}| \geq \xi(\mu n)^f$. We view $\mathcal{Q}_e$ as a $f$-graph and consider the random subgraph $\mathcal{Q}'_e$ containing all $Q \in \mathcal{Q}_e$ such that $(\mathcal{Q}'_e) \setminus \{e\} \subseteq H$. For each $Q \in \mathcal{Q}_e$, we have
\[
\mathbb{P}(Q \in \mathcal{Q}'_e) \geq \nu^{(r+1)(f+r)-1} \geq \nu^{(f+1)},
\]
thus $\mathbb{E}|\mathcal{Q}'_e| \geq \nu^{(f+1)}(\xi(\mu n))^f$. Using Corollary 5.14 and a union bound, we conclude that whp $|\mathcal{Q}'_e| \geq 2\xi(\mu n)^f$ for all $e \in G^{(r)}$. Assuming that this holds for $H$, Proposition 5.7 implies that for any admissible choices of $L$ and $O$, (S3) still holds.

Finally, we check (S4). Let $S \in \mathcal{S}$, $h \in [r-i]_0$ and $B \subseteq G(S)^{(h)}$ with $1 \leq |B| \leq 2h$. By assumption, $G_{S,B} := \bigcap_{b \in B} G(S \cup b)[U_S]$ is an $(\varepsilon, \xi, f-i-h, r-i-h)$-complex. We intend to apply Proposition 5.18 with $i + h + 1, G[U_S \cup S \cup \bigcup B], (\mathcal{P}_r, \mathcal{P}_f)[G^{(r)}][U_S \cup S \cup \bigcup B], b \cup B : b \in B$, $\nu^{r+1}, \varepsilon^{2/3}$ playing the roles of $i, G, \mathcal{P}, B, p, \gamma$. Note that for every $b \in B$ and all $e \in G^{(r-i-h)}_{S,B, B}$, $S \cup b \cup e$ is $\mathcal{S}$-important and $\tau_r(S \cup b \cup e) = (|S \cup b \cup e| \cap U_S) = |b \cap U_S| + r-i-h$. Hence, $S \cup b \cup e \in \mathcal{P}_r([b \cap U_S] + r-i-h+1)$. Thus, condition (I) in Proposition 5.18 is satisfied. Moreover, (II) is also satisfied because of $(P''_5)$ in Proposition 10.12. Therefore, by Proposition 5.18, with probability at least $1 - e^{-|U_S|^{1/8}}$, for any $L \subseteq G^{(r)}$ with $\Delta(L) \leq \varepsilon n \leq 2\varepsilon |U_S|/\mu \leq \varepsilon^{2/3}|U_S|$ and any $(r+1)$-graph $O$ on $V(G)$ with $\Delta(O) \leq \varepsilon n \leq f^{-5r}\varepsilon^{2/3}|U_S|$, we have that $\bigcap_{b \in B} G^{(r)}(S \cup b)[U_S]$ is a $(\sqrt{\varepsilon}, A', f-i-h, r-i-h)$-complex. A union bound now shows that with probability at least $1 - e^{-n^{1/10}}$, (S4) holds.

Thus, there exists an $H$ with the desired properties. 

\[\square\]
We also need a similar result which ‘sparsifies’ the neighbourhood complexes of an $i$-system.

**Lemma 10.21.** Let $1/n \ll \varepsilon \ll \mu, \beta, \xi, 1/f$ and $1 \leq i < r < f$. Let $\xi' := 0.9\xi^8f$. Let $G$ be a complex on $n$ vertices and let $S$ be an $i$-system in $G$ such that $G$ is $r$-exclusive with respect to $S$. Let $U$ be a $\mu$-focus for $S$. Suppose that

$$G(S)[U_S]$$

is an $(\varepsilon, \xi, f-i, r-i)$-supercomplex for every $S \in \mathcal{S}$.

Then there exists a subgraph $H \subseteq G^{(r)}$ with $\Delta(H) \leq 1.1\beta n$ and the following property: for all $L \subseteq G^{(r)}$ with $\Delta(L) \leq \varepsilon n$ and all $(r+1)$-graphs $O$ on $V(G)$ with $\Delta(O) \leq \varepsilon n$, the following holds for $G' := G[H \triangle \Delta L] - O$:

$$G'(S)[U_S]$$

is a $((\sqrt{\varepsilon}, \xi', f-i, r-i))$-supercomplex for every $S \in \mathcal{S}$.

**Proof.** Choose $H$ randomly by including each $e \in G^{(r)}$ independently with probability $\beta$. Clearly, $\Delta(H) \leq 1.1\beta n$. Now, consider $S \in \mathcal{S}$. Let $h \in [r-i]_0$ and $B \subseteq G(S)[U_S]^{[h]}$ with $1 \leq |B| \leq 2^h$. By assumption, $G_{S,B} := \cap_{b \in B} G(S)[U_S](b) = \cap_{b \in B} G(S \cup b)[U_S]$ is an $(\varepsilon, \xi, f-i-h, r-i-h)$-complex. Proposition 5.18 (applied with $G[U_S \cup S \cup B] = G_1, \{b \cup S : b \in B\}, i+h, \{G_1^{(r)}\}, \beta, \varepsilon^{2/3}$ playing the roles of $G, B, i, \mathcal{P}, \rho, \gamma$) implies that with probability at least $1 - e^{-|U_S|^{1/4}}$, $H$ has the property that for all $L \subseteq G^{(r)}$ with $\Delta(L) \leq \varepsilon n \leq \varepsilon^{2/3}|U_S|$ and all $(r+1)$-graphs $O$ on $V(G)$ with $\Delta(O) \leq \varepsilon n$, $G'(S)[U_S]_b$ is a $(\sqrt{\varepsilon}, \xi', f-i-h, r-i-h)$-complex.

Therefore, applying a union bound to all $S \in \mathcal{S}$, $h \in [r-i]_0$ and $B \subseteq G(S)[U_S]^{[h]}$ with $1 \leq |B| \leq 2^h$, we conclude that whp $H$ has the property that for all $L \subseteq G^{(r)}$ with $\Delta(L) \leq \varepsilon n$ and all $(r+1)$-graphs $O$ on $V(G)$ with $\Delta(O) \leq \varepsilon n$, $G'(S)[U_S]$ is a $((\sqrt{\varepsilon}, \xi', f-i, r-i))$-supercomplex for every $S \in \mathcal{S}$. Thus, there exists an $H$ with the desired properties. \hfill $\square$

The final tool that we need is the following lemma. Given a setup in a supercomplex $G$ and an $i'$-extension $T$ of the respective $i$-system $S$, it allows us to find a new focus $U'$ for $T$ and a suitable partition pair which together form a new setup in the complex $G'$ (which is the complex we look at after all edges with type less than $r-i$ have been covered).

**Lemma 10.22.** Let $1/n \ll \varepsilon \ll \rho \ll \mu, \xi, 1/f$ and $0 \leq i < i' < r < f$. Let $G$ be a complex on $n$ vertices and suppose that $\mathcal{S}, \mathcal{U}, (\mathcal{P}_r, \mathcal{P}_{i'})$ form an $(\varepsilon, \mu, \xi, f, r, i)$-setup for $G$. For $r' \geq r$, let $\tau_{r'}$ be the type function of $G^{(r')}$, $\mathcal{S}, \mathcal{U}$. Let $\mathcal{T}$ be the $i'$-extension of $\mathcal{S}$ in $G$ around $\mathcal{U}$, and let

$$G' := G - \{e \in G^{(r)} : e \text{ is } \mathcal{S}\text{-important and } \tau_{r'}(e) < r - i'\}.$$

Then there exist $\mathcal{U}', \mathcal{P}_r', \mathcal{P}_{i'}$ with the following properties:

(i) $\mathcal{U}'$ is a $(\mu, \rho, r)$-focus for $\mathcal{T}$ such that $U_T \subseteq U_{\mathcal{T}|\mathcal{S}}$ for all $T \in \mathcal{T}$;

(ii) $\mathcal{T}, \mathcal{U}', (\mathcal{P}_r', \mathcal{P}_{i'})$ form a $(1.1\varepsilon, \mu, \rho, \tau_{r'}^{-1}(\xi, f, r, i')$-setup for $G'$;

(iii) $G'(T)|U_T$ is a $(1.1\varepsilon, 0.9\xi, f - i', r - i')$-supercomplex for every $T \in \mathcal{T}$.

**Proof.** Let $\ell := r - i'$. Let $Y \subseteq G^{(f)}$ and $A \subseteq [0, 1]^{(r+1) \times (r+1)}$ be such that (S1)–(S4) hold for $G, \mathcal{S}, \mathcal{U}, (\mathcal{P}_r, \mathcal{P}_{i'})$. We choose $\mathcal{U}'$ randomly as follows: for every $T \in \mathcal{T}$ we let $U_T$ be a random subset of $U_{\mathcal{T}|\mathcal{S}}$, obtained by including each $x \in U_{\mathcal{T}|\mathcal{S}}$ with probability $\rho$, and all these choices are made independently. Let $\mathcal{U}' := (U_T)_{T \in \mathcal{T}}$. Clearly, $\mathcal{U}'$ is a focus for $\mathcal{T}$ and $U_T \subseteq U_{\mathcal{T}|\mathcal{S}}$ for all $T \in \mathcal{T}$. We will prove that (i)–(iii) hold whp.

By Proposition 10.5, the following hold:

(a) $G'$ is $r$-exclusive with respect to $\mathcal{T}$;

(b) for all $e \in G$ with $|e| \geq r$, we have

$$e \notin G' \iff e \text{ is } \mathcal{S}\text{-important and } \tau_{r'}(e) < |e| - i';$$

(c) for $r' \geq r$, the $\mathcal{T}$-important elements of $G^{(r')}$ are precisely the elements of $\tau_{r'}^{-1}(r' - i')$. 

For $r' \geq r$, property (a) allows us to consider the type function $\tau_{r'}$ of $G^{(r')}$, $T$, $\mathcal{U}'$. As a consequence of (b), we have for each $r' \geq r$ that

$$G^{(r')} = G^{(r')} \setminus \bigcup_{k=0}^{r'-i'-1} \tau_{r'}^{-1}(k).$$

In what follows, we define a suitable $(r, f)$-partition pair $(\mathcal{P}_r^*, \mathcal{P}_f^*)$ of $G'$. Recall that every element of a class from $\mathcal{P}_r([i])$ and $\mathcal{P}_f([i])$ is $S$-unimportant, and thus $T$-unimportant as well. By (10.8) and (c), the $T$-unimportant $r$-sets of $G'$ that are $S$-important are precisely the elements of $\tau_{r}^{-1}(r-i), \ldots, \tau_{r}^{-1}(r+i)$, and the $T$-unimportant $f$-sets of $G'$ that are $S$-important are precisely the elements of $\tau_{f}^{-1}(f-r+i), \ldots, \tau_{f}^{-1}(f-r-i)$. Thus, we aim to attach these classes to $\mathcal{P}_r([i])$ and $\mathcal{P}_f([i])$, respectively, in order to obtain partitions of the $T$-unimportant $r$-sets and $f$-sets of $G'$. When doing so, we reverse their order. This will ensure that the new partition pair is again upper-triangular (cf. Figure 2).

Define

$$\mathcal{P}_r^* := \mathcal{P}_r([i]) \cup (\tau_{r}^{-1}(r-i), \ldots, \tau_{r}^{-1}(r+i)), \quad \mathcal{P}_f^* := \mathcal{P}_f([i]) \cup (\tau_{f}^{-1}(f-i), \ldots, \tau_{f}^{-1}(f-r+i)).$$

Claim 1: $(\mathcal{P}_r^*, \mathcal{P}_f^*)$ is admissible with respect to $G'$, $T$, $\mathcal{U}'$.

**Proof of claim:** By (10.8) and (c), we have that $\mathcal{P}_r^*$ is a partition of the $T$-unimportant elements of $G^{(r)}$ and $\mathcal{P}_f^*$ is a partition of the $T$-unimportant elements of $G^{(f)}$. Moreover, note that $|\mathcal{P}_r^*| = i + (r - i - \ell) = i'$ and $|\mathcal{P}_f^*| = i + (f - i) - (f - r + \ell) = i'$, so (P1) holds.

We proceed with checking (P3). By (c), $\tau_{r}^{-1}(\ell)$ consists of all $T$-important edges of $G^{(r)}$, and $\tau_{f}^{-1}(f - r + \ell)$ consists of all $T$-important $f$-sets of $G^{(f)}$. Thus, $(\mathcal{P}_r^* \cup \{\tau_{r}^{-1}(\ell)\}, \mathcal{P}_f^* \cup \{\tau_{f}^{-1}(f - r + \ell)\})$ clearly is an $(r, f)$-partition pair of $G'$. If $0 \leq k' < \ell' \leq i' - i$, then no $Q \in \tau_{r}^{-1}(f - i - k')$ contains any element from $\tau_{r}^{-1}(r - i - \ell')$ by (10.6), so $(\mathcal{P}_r^* \cup \{\tau_{r}^{-1}(\ell)\}, \mathcal{P}_f^* \cup \{\tau_{f}^{-1}(f - r + \ell)\})$ is upper-triangular (cf. Figure 2).

It remains to check (P2). Let $T \in \mathcal{T}$, $h' \in [r - i]_0$ and $B' \subseteq G'(T)^{(h')}$ with $1 \leq |B'| \leq 2^{h'}$. Let $S := T \setminus \{S\}$, let $h := h' + i - i \in [r - i]_0$ and $B := \{(T \setminus S) \cup b' : b' \in B'\}$. Clearly, $B \subseteq G(S)^{(h)}$ with $1 \leq |B| \leq 2^{h}$. Thus, by (P5') in Proposition 10.12, we have for all $E \in \mathcal{P}_r$ that there exists $D(S, B, E) \in \mathcal{N}_0$ such that for all $Q \in \bigcap_{b \in B} G(S \cup b)[U_S]^{(f - i - h)}$, we have that

$$\{|e \in E : \exists b \in B : e \subseteq S \cup b \cup Q\} = D(S, B, E).$$

For each $E \in \mathcal{P}_r^*$, define $D'(T, B', E) := D(S, B, E)$. Thus, since $U_T \subseteq U_S$, we have for all $Q \in \bigcap_{b' \in B'} G'(T \cup b')[U_T]^{(f - i' - h')}$ that

$$\{|e \in E : \exists b' \in B' : e \subseteq T \cup b' \cup Q\} = D'(T, B', E).$$
Let \((\mathcal{P}_r^r, \mathcal{P}_r^{f})\) be the \((r, f)\)-partition pair of \(G^r\) induced by \((\mathcal{P}_r^r, \mathcal{P}_r^{f})\) and \(U^r\). Recall that \(\tau_r\) denotes the type function of \(G^{(r)}\), \(T, U^r\) (for any \(r' \geq r\)). Define the matrix \(A' \in [0, 1]^{(r+1) \times (f+1)}\) such that the following hold:

- For all \(E \in \mathcal{P}_r^r\) and \(Q \in \mathcal{P}_r^{f}\), let \(A'(E, Q) := A(E, Q)\).
- For all \(\ell' \in [r - i']_0\) and \(Q \in \mathcal{P}_r^{f}\), let \(A'(\tau_r^{-1}(\ell'), Q) := 0\).
- For all \(E \in \mathcal{P}_r^r\) and \(k' \in [f - i]'_0\), define
  \[A'(E, \tau_r^{-1}(k')) := \binom{f - i', \rho, k'}{A(E, \tau_r^{-1}(f - r + \ell'))}\]
- For all \(\ell' \in [r - i']_0, k' \in [f - i]'_0\), let
  \[A'((\tau_r^{-1}(\ell'), \tau_r^{-1}(k')) := \binom{f - r, \rho, k' - \ell') A(\tau_r^{-1}(\ell), \tau_r^{-1}(f - r + \ell'))\].

Claim 2: \(\min\{\|r - i' + 1(A')\| \geq \rho^{f - r} \xi\).

**Proof of claim:** Let
\[
a'_1 := \min_{E \in [r - i']_0} A'(\tau_r^{-1}(\ell'), \tau_r^{-1}(\ell')) \quad \text{and} \quad a'_2 := \min_{E \in [r - i']_0} A'(\tau_r^{-1}(\ell'), \tau_r^{-1}(f - r + \ell')).
\]
Observe that \(\min\{\|r - i' + 1(A')\| \geq \min\{\min\{\|r - i' + 1(A), a'_1, a'_2\| \geq (1 - \rho)^{f - r} \xi \quad \text{and} \quad a'_2 \geq \rho^{f - r} \xi\}, \text{the claim follows.}

We now prove in a series of claims that (i)--(iii) hold w.p. \(\text{by Lemma 10.7 \text{ (applied with \(T, (U_T)_{T \in T} \text{ playing the roles of \(S, U\), \(U^r\) is a \((\mu, \rho, r)\)-focus for \(T\), so (i) holds. In particular, \(w_{U^r}\) is a \(\mu_{U^r}\)-focus for \(T\), implying that (S1) holds for \(G^r\) with \(T, U^r\) and \((P_r, P_r')\). We now check (S2) \text{and (S4) \text{ and (iii).}}

Claim 3: \(\text{Whp } G^r[Y] \text{ is } (1.1) \text{, } A', f, r)\)-regular with respect to \((P_r, P_r[Y]) \text{ (cf. (S2)).)}

**Proof of claim:** By definition of \((P_r^r, P_r^{f+r})\), we have for all \(E \in P_r^r \cup \{\tau_r^{-1}(\ell)\}\) and \(Q \in (P_r^{f+r} \cup \{\tau_r^{-1}(f - r + \ell)\})[Y]\) that \(E \in P_r\) and \(Q \in P_r[Y]\). Since \(G[Y]\) is \((\xi, A, f, r)\)-regular with respect to \((P_r, P_r[Y])\), we have thus for all \(e \in E\) that
\[
|Q(e)| = (A(E, Q, e) \pm \xi) n^{f-r}. \tag{10.11}
\]

We have to show that for all \(E \in P_r^r, Q \in P_r^{f+r}[Y]\) and \(e \in E\), we have \(|Q(e)| = (A(E, Q, e) \pm 1.1 \xi) n^{f-r}\). We distinguish four cases as in the definition of \(A'\).

Firstly, for all \(E \in P_r^r, Q \in P_r^{f+r}[Y]\) and \(e \in E\), we have by (10.11) that \(|Q(e)| = (A(E, Q) \pm \xi) n^{f-r} = (A(E, Q, e) \pm \xi) n^{f-r}\) with probability \(1\).

Also, for all \(\ell' \in [r - i]'_0, Q \in P_r^{f+r}[Y]\) and \(e \in \tau_r^{-1}(\ell')\), we have \(|Q(e)| = 0 = A'(\tau_r^{-1}(\ell'), Q) n^{f-r}\) with probability \(1\).

Let \(E \in P_r^r \cup \{\tau_r^{-1}(\ell)\}\) and consider \(e \in E\). Let \(Q_{e} := (Y \cap \tau_r^{-1}(f - r + \ell))(e)\). By (10.11), we have that \(|Q_{e}| = (A(E, \tau_r^{-1}(f - r + \ell)) \pm \xi) n^{f-r}\).

First, assume that \(e \in E \in P_r^r\). For each \(k' \in [f - i]'_0\), we consider the random subgraph \(Q_{e}^{k'}\) of \(Q_{e}\) that contains all \(Q \in Q_{e}\) with \(Q \cup e \in \tau_r^{-1}(k')\). Hence, \(Q_{e}^{k'} = (Y \cap \tau_r^{-1}(k')(e))\). For each \(Q \in Q_{e}\), there are unique \(T_Q \in T\) and \(S_Q \in S\) with \(S_Q \subseteq T_Q \subseteq Q \cup e\) and \((Q \cup e) \setminus T_Q \subseteq U_{S_Q}\).

For each \(Q \in Q_{e}\), we then have
\[
\mathbb{P}(Q \in Q_{e}^{k'}) = \mathbb{P}(\tau_r^{-1}(Q \cup e) = k' = \mathbb{P}([Q \cup e) \cap U_{T_Q}] = k') = \binom{f - i', \rho, k'}{n^{f-r}}.
\]
Thus, \(E|Q_{e}^{k'}| = \binom{f - i', \rho, k'}{Q_{e}}\). For each \(T \in T\), let \(Q_T\) be the set of all \(Q \in Q_{e}\) for which \(T_Q = T\). Since \(e \in T\), we have \(|T \setminus e| > 0\) and thus \(|Q_T| \leq n^{f-r-1}\) for all \(T \in T\). Thus \(Q_{e}\) can partition \(Q_{e}\) into \(n^{f-r-1}\) subgraphs such that each of them intersects each \(Q_T\) in at most one element. For all \(Q \) lying in the same subgraph, the events \(Q \in Q_{e}^{k'}\) are now independent. Hence, by Lemma 5.12, we conclude that with probability at least \(1 - e^{-n^{1/6}}\) we
have that
\[
|Q_e'| = (1 \pm \varepsilon^2)\mathbb{E}[Q_e'] = (1 \pm \varepsilon^2)\text{bin}(f - i', \rho, k')|Q_e|
\]
(10.12)
\[
= (1 \pm \varepsilon^2)\text{bin}(f - i', \rho, k')(A(\mathcal{E}, \tau_f^{-1}(f - r + \ell)) \pm \varepsilon)n^{f-r}
\]
\[
= (A'(\mathcal{E}, \tau_f^{-1}(k')) \pm 1.1\varepsilon)n^{f-r}.
\]
(Technically, we can only apply Lemma 5.12 if $|Q_e| \geq 0.1e^{n^{f-r}}$, say. Note that (10.12) holds trivially if $|Q_e| \leq 0.1e^{n^{f-r}}$.)

Finally, consider the case $e \in \mathcal{E} = \tau_r^{-1}(\ell)$. By (c), $e$ is $T$-important, so let $T \subseteq T$ be such that $T \subseteq e$. Note that for every $Q \in Q_e$, we have $(e \setminus T) \cup Q \subseteq U_S$, where $S := T|_S$. For every $x \in [f - r]_0$, let $Q_e'$ be the random subgraph of $Q$, that contains all $Q \in Q_e$ with $|Q \cap U_T| = x$.

By the random choice of $U_T$, for each $Q \in Q$ and $x \in [f - r]_0$, we have
\[
P(Q \in Q_e) = \text{bin}(f - r, \rho, x).
\]

Using Corollary 5.14 we conclude that for $x \in [f - r]_0$, with probability at least $1 - e^{-n^{f-r}}$ we have that
\[
|Q_e'| = (1 \pm \varepsilon^2)\mathbb{E}[Q_e'] = (1 \pm \varepsilon^2)\text{bin}(f - r, \rho, x)|Q_e|
\]
\[
= (1 \pm \varepsilon^2)\text{bin}(f - r, \rho, x)(A(\tau_r^{-1}(\ell), \tau_f^{-1}(f - r + \ell)) \pm \varepsilon)n^{f-r}
\]
\[
= (\text{bin}(f - r, \rho, x)A(\tau_r^{-1}(\ell), \tau_f^{-1}(f - r + \ell)) \pm 1.1\varepsilon)n^{f-r}.
\]
Thus for all $\ell' \in [r - i']_0$, $k' \in [f - i']_0$ and $e \in \tau_r^{-1}(\ell')$ with $k' \geq \ell'$, with probability at least $1 - e^{-n^{f-r}}/6$ we have
\[
|(Y \cap \tau_f^{-1}(k'))(e)| = |Q_e'| = (A'(\tau_r^{-1}(\ell'), \tau_f^{-1}(k')) \pm 1.1\varepsilon)n^{f-r},
\]
and if $\ell' > k'$ then trivially $|(Y \cap \tau_f^{-1}(k'))(e)| = 0 = A'(\tau_r^{-1}(\ell'), \tau_f^{-1}(k'))n^{f-r}$. Thus, a union bound implies the claim.

**Claim 4:** Whp every $T$-unimportant $e \in G^{(r)}$ is contained in at least $0.9\xi(\rho\mu)|T$-unimportant $Q \in G^{(r)}$, and for every $T$-important $e \in G^{(r)}$ with $e \supseteq T \in T$, we have $|G^{(r)}(e)[U_T]| \geq 0.9\xi(\rho\mu)|T|$. (cf. (S3)).

**Proof of claim:** Let $e \in G^{(r)}$ be $T$-unimportant. By (b) and (c), we thus have that $e$ is $S$-unimportant or $\tau_r(e) > \ell$. In the first case, we have that $e$ is contained in at least $\xi(\mu)|T|$. $S$-unimportant $Q \in G^{(r)}$ by (S3) for $U, G, S$. But each such $Q$ is clearly $T$-unimportant as well and contained in $G^{(r)}$. If the second case applies, assume that $e$ contains $S \subseteq S$. By (S3) for $G, S, U$, we have that $|G^{(r)}(e)[U_S]| \geq \xi(\mu)|T|$. For every $Q \in G^{(r)}(e)[U_S]$, we have that $\tau_f + (Q \cup e) \supseteq (Q \cup e) \cap U_S = f + \tau_r(e) > f + \ell$. Thus, (b) implies that $Q \cup e \in G^{(r)}$, and by (c) we have that $Q \cup e$ is $T$-unimportant. Altogether, every $T$-unimportant edge $e \in G^{(r)}$ is contained in at least $\xi(\mu)|T| \geq 0.9(\rho\mu)|T|$-unimportant $Q \in G^{(r)}$. Let $e \in G^{(r)}$ be $T$-important. Assume that $e$ contains $T \in T$ and let $S := T|_S$. By (S3) for $G, S, U$, we have that $|G^{(r)}(e)[U_S]| \geq \xi(\mu)|T|$. As before, for every $Q \in G^{(r)}(e)[U_S]$, we have $Q \subseteq e \in G^{(r)}$. Moreover, $P(Q \subseteq U_T) = \rho|T|$. Thus, by Corollary 5.14, with probability at least $1 - e^{-n^{f-r}}$ we have that $|G^{(r)}(e)[U_T]| \geq 0.9\xi(\rho\mu)|T|$. A union bound hence implies the claim.

**Claim 5:** Whp for all $T \subseteq T$, $h' \in [r - i']_0$ and $B' \subseteq G^{(r)}(h')$ with $1 \leq |B'| \leq 2h'$ we have that
\[
\bigcap_{B' \subseteq B' \subseteq G^{(r)}(h')} |U_B|[U_S] \text{ is an } (1.1\varepsilon, 0.9\xi, f - i' - h', r - i' - h')-complex (cf. (S4) and (iii)).
\]

**Proof of claim:** Let $T \subseteq T$, $h' \in [r - i']_0$ and $B' \subseteq G^{(r)}(h')$ with $1 \leq |B'| \leq 2h'$. Let $S := T|_S$. We claim that
\[
\bigcap_{B' \subseteq B'} G^{(r)}(T \cup b'|U_S) \text{ is an } (e, \xi, f - i' - h', r - i' - h')-complex.
\]
If $\bigcap_{B' \subseteq B'} G^{(r)}(T \cup b'|U_S)$ is empty, then there is nothing to prove, thus assume the contrary. We claim that we must have $b' \subseteq U_S$ for all $b' \subseteq B'$. Indeed, let $b' \subseteq B'$ and $g_0 \in G^{(r)}(T \cup$
Since, $g_0 \cup T \cup b' \in G^{(r)}$. By (b), we must have $|(g_0 \cup T \cup b') \cap U_S| \geq |g_0 \cup T \cup b'|-i'$. But since $T \cap U_S = \emptyset$, we must have $b' \subseteq U_S$.

Let $h = h' + i' - i \in [r-i]_0$ and $B := \{(T \setminus S) \cup b' : b' \in B'\} \subseteq G(S)^{(h)}$. (S4) for $U,G,S$ implies that $\bigcap_{b \in B} G(S \cup b)[U_S]$ is an $(\varepsilon, \xi, f-i-h, r-i-h)$-complex. To prove (10.13), it thus suffices to show that $G(T \cup b')[U_S]^{(r)} = G'(T \cup b')[U_S]^{(r)}$ for all $r' \geq r-i-h$ and $b' \in B'$. To this end, let $b' \in B'$, $r' \geq r-i-h$ and suppose that $g \in G(T \cup b')[U_S]^{(r')}$.

Observe that $|(g \cup T \cup b') \cap U_S| = |g \cup T \cup b'|-i'$, so (b) implies that $g \cup T \cup b' \in G'$ and thus $g \in G'(T \cup b')[U_S]^{(r')}$. This proves (10.13).

By Proposition 5.16, with probability at least $1-e^{-|U_S|^8}$, $\bigcap_{b' \in B'} G'(T \cup b')[U_T]$ is an $(1.1 \varepsilon, 0.9 \xi, f-i'-h', r-i'-h')$-complex.

Applying a union bound to all $T \in T$, $h' \in [r-i']_0$ and $B' \subseteq G'(T)^{(h')}$ with $1 \leq |B'| \leq 2^{hl'}$ then establishes the claim.

By the above claims, $U'$ satisfies (S2)–(S4) whp and thus (ii). Moreover, Claim 5 implies that whp (iii) holds. Thus, the random choice $U'$ satisfies (i)–(iii) whp. 

\[ \square \]

### 10.4. Proof of the Cover down lemma.

In this subsection, we state and prove the Cover down lemma for setups and deduce the Cover down lemma (Lemma 7.7).

**Definition 10.23.** Let $F$ and $G$ be $r$-graphs, let $S$ be an $i$-system in $V(G)$, and let $U$ be a focus for $S$. We say that $G$ is $F$-divisible with respect to $S,U$, if for all $S \subseteq S$ and all $T \subseteq V(G) \setminus S$ with $|T| \leq r-i-1$ and $|T \setminus U_S| \geq 1$, we have $\operatorname{Deg}(F)_{i+|T|} \mid G(S \cup T)$.

Note that if $G$ is $F$-divisible, then it is $F$-divisible with respect to any $i$-system and any associated focus.

Recall that a setup for $G$ was defined in Definition 10.18, and $G$ being $(\xi,f,r)$-dense with respect to $H \subseteq G^{(r)}$ in Definition 7.6. We will prove the Cover down lemma for setups by induction on $r-i$. We will deduce the Cover down lemma by applying this lemma with $i = 0$.

**Lemma 10.24.** (Cover down lemma for setups). Let $1/n \ll 1/k \ll \gamma \ll \varepsilon \ll \nu \ll \mu, \xi, 1/f$ and $0 \leq i < r < f$. Let $F$ be a weakly regular $r$-graph on $f$ vertices. Assume that $(*)$ is true for all $\ell \in [r-i-1]$. Let $G$ be a complex on $n$ vertices and suppose that $S,U,(P_r,P_f)$ form an $(\varepsilon, \mu, \xi, f, r, i)$-setup for $G$. For $r' \geq r$, let $\tau_{r'}$ denote the type function of $G^{(r')}$, $S,U$. Then the following hold.

(i) Let $\tilde{G}$ be a complex on $V(G)$ with $G \subseteq \tilde{G}$ such that $\tilde{G}$ is $(\varepsilon, f,r)$-dense with respect to $G^{(r)} - \tau_{r-1}(0)$. Then there exists a subgraph $H^{*} \subseteq G^{(r)} - \tau_{r-1}(0)$ with $\Delta(H^{*}) \leq \nu n$ such that for any $L^{*} \subseteq \tilde{G}^{(r)}$ with $\Delta(L^{*}) \leq \gamma n$ and $H^{*} \cup L^{*}$ being $F$-divisible with respect to $S,U$ and any $(r+1)$-graph $O^{*}$ on $V(G)$ with $\Delta(O^{*}) \leq \gamma n$, there exists a $\kappa$-well separated $F$-packing in $\tilde{G}[H^{*} \cup L^{*}] - O^{*}$ which covers all edges of $L^{*}$, and all $S$-important edges of $H^{*}$ except possibly some from $\tau_{r-1}(r-i)$.

(ii) If $G^{(r)}$ is $F$-divisible with respect to $S,U$ and the setup is diagonal-dominant, then there exists a $2\kappa$-well separated $F$-packing in $G$ which covers all $S$-important $r$-edges except possibly some from $\tau_{r-1}(r-i)$.

Before proving Lemma 10.24, we show how it implies the Cover down lemma (Lemma 7.7). Note that we only need part (i) of Lemma 10.24 to prove Lemma 7.7. (ii) is used in the inductive proof of Lemma 10.24 itself.

**Proof of Lemma 7.7.** Let $S := \{\emptyset\}$, $U := \{U\}$ and let $(P_r,P_f)$ be the $(r,f)$-partition pair of $G,U$. By Proposition 10.19, $S,U,(P_r,P_f)$ form a $(\varepsilon, \mu^{1-r}\xi, f, r, 0)$-setup for $G$. We can thus apply Lemma 10.24(i) with $\mu^{1-r}\xi$ playing the role of $\xi$. Recall that all $r$-edges of $G$ are $S$-important. Moreover, let $\tau_{r}$ denote the type function of $G^{(r)}$, $S,U$. We then have $\tau_{r-1}(0) = G^{(r)}[\bar{U}]$ and $\tau_{r-1}(r) = G^{(r)}[U]$, where $\bar{U} := V(G) \setminus U$. 

\[ \square \]
Proof of Lemma 10.24. The proof is by induction on \( r - i \). For \( i = r - 1 \), we will prove the statement directly. For \( i < r - 1 \), we assume that the statement is true for all \( i' \in \{i+1, \ldots, r-1\} \). We will first prove (i) using (ii) inductively, and then derive (ii) from (i) (for the same value of \( r - i \)).

Proof of (i).
If \( i < r - 1 \), choose new constants \( \nu_1, \rho_1, \beta_1, \ldots, \nu_{r-i-1}, \rho_{r-i-1}, \beta_{r-i-1} \) such that

\[
1/n \ll 1/\kappa \ll \gamma \ll \varepsilon \ll \nu_1 \ll \rho_1 \ll \beta_1 \ll \cdots \ll \nu_{r-i-1} \ll \rho_{r-i-1} \ll \beta_{r-i-1} \ll \nu \ll \mu, \xi, 1/f.
\]

For every \( \ell \in [r - i - 1] \), let

\[
G_{\ell} := G - \{e \in G_{i}^{(r)} : e \text{ is } S\text{-important and } \tau_\ell(e) < \ell\}.
\]

For every \( i' \in \{i+1, \ldots, r-1\} \), let \( T' \) be the \( i' \)-extension of \( S \) in \( G \) around \( U \). By Proposition 10.5, the following hold for all \( i' \in \{i+1, \ldots, r-1\} \):

(I) \( G_{r-i'} \) is \( r \)-exclusive with respect to \( T' \);

(II) the elements of \( \tau_{r-i'}^{-1}(r-i') \) are precisely the \( T' \)-important elements of \( G_{i}^{(r)} \).

By Lemma 10.22, for every \( i' \in \{i+1, \ldots, r-1\} \), there exist \( U', P_{i'}, P_{i'}' \) such that the following hold:

(a) \( U' \) is a \((\mu, \rho_{r-i'}, r)\)-focus for \( T' \) such that \( U_T \subseteq U_{T'|S} \) for all \( T \in T' \);

(b) \( T', U', (P_{i'}, P_{i'})' \) form a \((1.1\varepsilon, \rho_{r-i'}^\ell, \rho_{r-i'}^\ell, \xi, f, r, i')\)-setup for \( G_{r-i'} \);

(c) \( G_{r-i'}(T)[U_T] \) is \((1.1\varepsilon, 0.9\xi, f - i', r - i')\)-supercomplex for every \( T \in T' \).

(1) allows us to consider the type function \( \tau_{r-i'} \cdot \) of \( G_{i}^{(r)} \). \( T', U' \).

Step 1: Reserving subgraphs
In this step, we will find a number of subgraphs of \( G_{i}^{(r)} - \tau_{r-i}^{-1}(0) \) whose union will be the \( r \)-graph \( H^r \) we seek in (i). Let \( G \) be a complex as specified in (i). Let \( H_0 \) be a subgraph of \( G_{i}^{(r)} - \tau_{r-i}^{-1}(0) \) with \( \Delta(H_0) \leq 1.1\beta_0 n \) such that for all \( e \in G_{i}^{(r)} \), we have

\[
|\tilde{G}(H_0 \cup \{e\}^{(r)}(e))| \geq 0.9\beta_0^{(f)} n^{f-r}.
\]

(\( H_0 \) will be used to greedily cover \( L^r \).) That such a subgraph exists can be seen by a probabilistic argument: let \( H_0 \) be obtained by including every edge of \( (G_{i}^{(r)} - \tau_{r-i}^{-1}(0)) \) with probability \( \beta_0 \). Clearly, \( \Delta(H_0) \leq 1.1\beta_0 n \). Also, since \( \tilde{G} \) is \((\varepsilon, f, r)\)-dense with respect to \( G_{i}^{(r)} - \tau_{r-i}^{-1}(0) \) by assumption, we have for all \( e \in \tilde{G}_{i}^{(r)} \) that

\[
E(\tilde{G}(H_0 \cup \{e\}^{(r)}(e))) = \beta_0^{(f)-1} |\tilde{G}((G_{i}^{(r)} - \tau_{r-i}^{-1}(0)) \cup \{e\})^{(r)}(e)| \geq \beta_0^{(f)-1} \varepsilon n^{f-r}.
\]

Using Corollary 5.14 and a union bound, it is then easy to see that whp \( H_0 \) satisfies (10.15) for all \( e \in G_{i}^{(r)} \).

Step 1.1: Defining ‘sparse’ induction graphs \( H_\ell \).
Consider \( \ell \in [r - i - 1] \) and let \( i' := r - \ell \). Let \( \xi_\ell := \nu_{\ell}^{i''} f + 1 \). By (b) and Lemma 10.20 (with \( G_{i}, 3\beta_{r-i}, \nu_{\ell}, \rho_{\ell}, \rho_{\ell}^{i''} \xi, i' \) playing the roles of \( G, \varepsilon, \mu, \xi, i, \)), there exists a subgraph \( H_\ell \subseteq G_{\ell}^{(r)} \) with \( \Delta(H_\ell) \leq 1.1\nu_{\ell} n \) and the following property: for all \( L \subseteq G_{\ell}^{(r)} \) with \( \Delta(L) \leq 3\beta_{r-i} n \) and every \((r+1)\)-graph \( O \) on \( V(G_{i}) \) with \( \Delta(O) \leq 3\beta_{r-i} n \), the following holds for \( G' := G_{i}/H_\ell \Delta L \): \( O \):

\[
T', U', (P_{i'}, P_{i'})' \text{ form a diagonal-dominant} \]

\[
(\sqrt{3\beta_{r-i}}, \rho_{\ell}, \xi, f, r, i')\text{-setup for } G'.
\]

Step 1.2: Defining ‘localised’ cleaning graphs \( I_\ell \).
Again, consider \( \ell \in [r - i - 1] \) and let \( i'' := r - \ell \). Let

\[
G_{\ell} := G_{\ell} - \{e \in G_{i}^{(r)} : e \text{ is } T'\text{-important and } \tau_{\ell,e}(e) < \ell\}.
\]

We claim that \( G_{\ell}^*(T)[U_T] = G_{\ell}(T)[U_T] \) for every \( T \in T' \). Indeed, consider any \( T \in T' \) and \( e \in G_{\ell}(T)[U_T] \). Hence, \( e \subseteq U_T \) and \( e \cup T \subseteq G_{\ell} \). We need to show that \( e \cup T \in G_{\ell}^* \), i.e. that there
is no $T'$-important $r$-subset $e'$ of $e \cup T$ with $\tau_{e,r}(e') < \ell$. However, if $e' \in \binom{e \cup T}{r}$ is $T'$-important, then $|e \cup T| \geq |e'| = r$ and since $G_\ell$ is $r$-exclusive with respect to $T'$ by (I), we must have $T \subseteq e'$. As $e' \setminus T \subseteq e \subseteq U_T$, we deduce that $\{e' \cap U_T, |e' \setminus T| = r - i' = \ell$.

Hence, by (e), for every $T \in \mathcal{T}'$, $G_\ell^c(T) |U_T|$ is a $(1.1 \xi, 0.9 \xi, f - i', r - i')$-supercomplex. Thus, by Lemma 10.21 (with $G_\ell^c, 3\mu, \rho, \beta_r, 0.9 \xi$ playing the roles of $G, \varepsilon, \rho, \beta, \xi$), there exists a subgraph $J_{\ell} \subseteq G_\ell^c(r)$ with $\Delta(J_{\ell}) \leq 1.1 \beta_r n$ and the following property: for all $L \subseteq G_\ell^c(r)$ with $\Delta(L) \leq 3\nu \ell n$ and every $(r + 1)$-graph $O$ on $V(G_\ell^c)$ with $\Delta(O) \leq 3\nu \ell n$, the following holds for $G^* := G_\ell^c |\ell \Delta L - O$:

\[(10.18) \quad G^*(T) |U_T| \text{ is a } (\sqrt{3\nu \ell}, 0.81 \xi \beta_r^{(8/7)}, f - i', r - i') \text{-supercomplex for every } T \in \mathcal{T}' \cdot \]

We have defined subgraphs $H_0, H_1, \ldots, H_{r-1}, J_1, \ldots, J_{r-1-1}$ of $G(r) - \tau_r^{-1}(0)$. Note that they are not necessarily edge-disjoint. Let $H_0^\ell := H_0$ and for all $\ell \in [r - i - 1]$ define inductively

$H_{\ell}^r := H_{\ell-1}^r \cup H_{\ell}$,

$H_{\ell}^r := H_{\ell-1}^r \cup H_{\ell} \cup J_{\ell} = H_{\ell}^r \cup J_{\ell}$,

$H^* := H^r_{r-i-1}$.

Clearly, $\Delta(H^r_{\ell}) \leq 2\beta_r n$ for all $\ell \in [r - i - 1]$ and $\Delta(H^r_{\ell}) \leq 2\nu \ell n$ for all $\ell \in [r - i - 1]$. In particular, $\Delta(H^r) \leq 2\beta_r n \leq \nu n$, as desired.

**Step 2: Covering down**

Let $L^*$ be any subgraph of $\tilde{G}(r)$ with $\Delta(L^*) \leq \gamma n$ such that $H^* \cup L^*$ is $F$-divisible with respect to $S, \mathcal{U}$, and let $O^* \subseteq \tilde{G}(r+1)$ with $\Delta(O^*) \leq \gamma n$. We need to find a $\kappa$-well separated $F$-packing $F$ in $\tilde{G}[H^* \cup L^*] - O^*$ which covers all edges of $L^*$, and covers all $S$-important edges of $H^*$ except possibly some from $\tau_r^{-1}(r - i)$. We will do so by inductively showing that the following holds for all $\ell \in [r - i]$.

(\#) \quad \text{There exists a } (3\ell \sqrt{\kappa}) \text{-well separated } F \text{-packing } F^r_{\ell-1} \text{ in } \tilde{G}[H^r_{\ell-1} \cup L^*] - O^* \text{ covering all edges of } L^*, \text{ and all } S \text{-important } e \in H^r_{\ell-1} \text{ with } \tau_r(e) < \ell.

Clearly, (\#)$_{r-i}$ establishes (i).

**Claim 1:** (\#)$_{1}$ is true.

**Proof of claim:** Let $H_0^r := H_0 \cup L^* = H_0^r \cup L^*$. By (10.15) and Proposition 5.7, for all $e \in L^*$ we have that

\[|\tilde{G}[H_0^r] - O^*|^{(f)}(e) \geq |\tilde{G}[H_0^r \cup e]^{(f)}(e)| - 2^f \gamma n^{f-r} \geq 0.8 \beta_0^{(1)}(n) \nu^{f-r}.\]

By Corollary 6.9, there is a 1-well separated $F$-packing $F^r_0$ in $\tilde{G}[H_0^r] - O^*$ covering all edges of $L^*$. Since $H^r_0$ does not contain any edges from $\tau^{-1}(0)$, $F^r_0$ satisfies (\#)$_{1}$.

If $i = r - 1$, we can take $F^r_0$ and complete the proof of (i). So assume that $i < r - 1$ and that Lemma 10.24 holds for larger values of $i$.

Suppose that for some $\ell \in [r - i - 1]$, $F^r_{\ell-1}$ satisfies (\#)$_{\ell}$. Let $i' := r - \ell > i$. We will now find a $3\sqrt{\kappa}$-well separated $F$-packing $F^r_{i'}$ in $\tilde{G}[H^r_{\ell}] - F^r_{\ell-1} - F^r_{\ell-1}^{(r+1)} - O^*$ such that $F^r_{i'}$ covers all edges of $H^r_{\ell} - F^r_{\ell-1}^{(r)}$ that belong to $\tau^{-1}(\ell)$.

Then $F^r_{i'} := F^r_{\ell-1} \cup F^r_{\ell} \cup G^r_{\ell}$ covers all edges of $L^*$ and all $S$-important $e \in H^r_{\ell}$ with $\tau_r(e) < \ell + 1$. By Fact 5.4(ii), $F^r_{i'}$ is $(3\ell \sqrt{\kappa} + 3\sqrt{\kappa})$-well separated, implying that (\#)$_{i'+1}$ is true.

Crucially, by (II), all the edges of $\tau^{-1}(\ell)$ that we seek to cover in this step are $T'$-important. We will obtain $F^r_{i'}$ as the union of $F^r_{i'}$ and $F^r_{i'}$ where

(COV1) $F^r_{i'}$ is a $2\sqrt{\kappa}$-well separated $F$-packing in $G[H^r_{\ell}] - F^r_{\ell-1} - F^r_{\ell-1}^{(r+1)} - O^*$ which covers all $T'$-important edges of $H^r_{\ell} - F^r_{\ell-1}^{(r)}$ except possibly some from $\tau^{-1}_r(\ell)$;

(COV2) $F^r_{i'}$ is a $\sqrt{\kappa}$-well separated $F$-packing in $G[H^r_{\ell}] - F^r_{\ell-1} - F^r_{\ell-1}^{(r+1)} - F^r_{\ell}^{(r)} - F^r_{\ell-1}^{(r+1)} - O^*$ which covers all $T'$-important edges of $H^r_{\ell} - F^r_{\ell-1}^{(r)} - F^r_{\ell}^{(r)}$. 

Since $\mathcal{F}_\ell^\dagger$ and $\mathcal{F}_\ell^\circ$ are $(r+1)$-disjoint, $\mathcal{F}_\ell := \mathcal{F}_\ell^\circ \cup \mathcal{F}_\ell^\dagger$ is $3\sqrt{r}$-well separated by Fact 5.4(ii). Clearly, $\mathcal{F}_\ell$ covers all $\mathcal{T}'$-important edges of $H'_\ell - \mathcal{F}_{\ell-1}^{(r)}$, as required. We will obtain $\mathcal{F}_\ell^\circ$ by using (ii) of this lemma inductively, and $\mathcal{F}_\ell^\dagger$ by an application of the Localised cover down lemma (Lemma 10.8).

Recall that $F$-divisibility with respect to $\mathcal{T}$, $\mathcal{U}$ was defined in Definition 10.23. Let $H''_\ell := H'_\ell - \mathcal{F}_{\ell-1}^{(r)}$.

**Claim 2:** $H''_\ell$ is $F$-divisible with respect to $\mathcal{T}', \mathcal{U}'$.

**Proof of claim:** Let $T \subseteq \mathcal{T}$ and $b' \subseteq V(G) \setminus T$ with $|b'| \leq r - i' - 1$ and $|b' \cap U_T| \geq 1$. We have to show that $\text{Deg}(F)_{i+|b'|} | (H''_\ell (T \cup b'))$. Let $S := T \setminus S$ and $b := b' \cup (T \setminus S)$. Hence, $|b| = |b'| + i' - i$.

Clearly, $b \subseteq V(G) \setminus S$, $|b| \leq r - i - 1$ and $|b \cap U_S| \geq |T \setminus S| \geq 1$. Hence, since $H''_\ell \cup L'$ is $F$-divisible with respect to $S, U$ by assumption, we have $\text{Deg}(F)_{i+|b|} | (H''_\ell \cup L') (S \cup b)$, and this implies that $\text{Deg}(F)_{i+|b'|} | ((H''_\ell \cup L') - \mathcal{F}_{\ell-1}^{(r)} (S \cup b))$. It is thus sufficient to show that

$$H''_\ell (T \cup b') = ((H''_\ell \cup L') - \mathcal{F}_{\ell-1}^{(r)} (S \cup b))$$

Clearly, we have $T \cup b' = S \cup b$ and $H''_\ell \subseteq H''_\ell - \mathcal{F}_{\ell-1}^{(r)}$. Conversely, observe that every $e \in H''_\ell \cup L'$ that contains $T \cup b'$ and is not covered by $\mathcal{F}_{\ell-1}^{(r)}$ must belong to $H''_\ell$. Indeed, since $e$ contains $T$, we have that $\tau_{r'}(e) \leq r - i' = \ell$, so $e \in H''_\ell$. Moreover, by (#) we must have $\tau_e(e) \geq \ell$. Hence, $\tau_e(e) = \ell$. But since $|b' \cap U_T| \geq 1$, we have $\tau_{r'}(e) < \ell$. By (10.17), $e \notin J_{r'}$. Thus, $e \in H''_\ell - \mathcal{F}_{\ell-1}^{(r)} = H''_\ell$. Hence, $H''_\ell (T \cup b') = ((H''_\ell \cup L') - \mathcal{F}_{\ell-1}^{(r)} (S \cup b))$. This implies the claim.

Let $L'_\ell := H''_\ell \setminus H'. \text{ So } H''_\ell = H' \cup L'_\ell$.

**Claim 3:** $L'_\ell \subseteq G^{(r)}_\ell$ and $\Delta(L'_\ell) \leq 3\beta_{\ell-1} n$.

**Proof of claim:** Suppose, for a contradiction, that there is $e \in H''_\ell \setminus H'$ with $e \notin G^{(r)}_\ell$. Since $H' \subseteq G^{(r)}_\ell$, we must have $e \in H''_\ell = H'_\ell - \mathcal{F}_{\ell-1}^{(r)}$. Thus, since $e$ is not covered by $\mathcal{F}_{\ell-1}^{(r)}$, (#) implies that $e$ is $S$-unimportant or $\tau_r(e) \geq \ell$, both contradicting $e \notin G^{(r)}_\ell$.

In order to see the second part, observe that $L'_\ell = ((H''_{\ell-1} \setminus H') - \mathcal{F}_{\ell-1}^{(r)}) \cup H' \subseteq H''_{\ell-1} \cup L'$ since $\mathcal{F}_{\ell-1}^{(r)} \subseteq L' \cup H''_{\ell-1}$. Thus, $\Delta(L'_\ell) \leq \Delta(H''_{\ell-1}) + \Delta(L') \leq 3\beta_{\ell-1} n$.

Note that Claim 3 implies that $H''_\ell \subseteq G^{(r)}_\ell$. Let $G^{ind}_{\ell,ind} := G_\ell[H''_\ell] - \mathcal{F}_{\ell-1}^{(r-1)} - 0^*$. By Fact 5.4(i) and (#), we have that $\Delta(F^{\leq \ell-1}(T') \cup \Omega^{\leq \ell-1}) \leq 3(\sqrt{3\beta_{\ell-1}}(f - r) + \gamma n \leq 2\gamma n$. Thus, by (10.16) and Claim 3, $\mathcal{T}', \mathcal{U}', (P_{r'}) \in [G^{ind}_{\ell,ind}]$ form a diagonal-dominant $(\sqrt{3\beta_{\ell-1}}, \rho_{\ell, \mu, \xi, \ell', r, i'})$-setup for $G^{ind}_{\ell,ind}$. We can thus apply Lemma 10.24(ii) inductively with the following objects/parameters:

<table>
<thead>
<tr>
<th>object/parameter</th>
<th>playing the role of</th>
</tr>
</thead>
<tbody>
<tr>
<td>$G$</td>
<td>$n$</td>
</tr>
<tr>
<td>$\gamma_{\ell,ind}$</td>
<td>$\sqrt{3\beta_{\ell-1}}(f - r) + \gamma n$</td>
</tr>
<tr>
<td>$\rho_{\ell, \mu, \xi, \ell', r, i'}$</td>
<td>$S'$</td>
</tr>
<tr>
<td>$T'$</td>
<td>$U'$</td>
</tr>
<tr>
<td>$(P_{r'}, P'<em>{r'}) \in [G^{ind}</em>{\ell,ind}]$</td>
<td>$\sqrt{\kappa}$</td>
</tr>
<tr>
<td>$f$</td>
<td>$r$</td>
</tr>
<tr>
<td>$F$</td>
<td>$r$</td>
</tr>
</tbody>
</table>

Since $G^{ind}_{\ell,ind} = H''_\ell$ is $F$-divisible with respect to $\mathcal{T}', \mathcal{U}'$ by Claim 2, there exists a $2\sqrt{3}$-well separated $F$-packing $\mathcal{F}_\ell^\circ$ in $G^{ind}_{\ell,ind}$ covering all $\mathcal{T}'$-important edges of $H''_\ell$ except possibly some from $\tau_{r'}^{-1}(r - i') = \tau_{r'}^{-1}(\ell)$. Note that $H''_\ell - H' \subseteq J_{r'}$ and that every $\mathcal{T}'$-important edge of $J_{r'}$ lies in $\tau_{r'}^{-1}(\ell)$. Thus $\mathcal{F}_\ell^\circ$ does indeed cover all $\mathcal{T}'$-important edges of $H''_\ell - \mathcal{F}_{\ell-1}^{(r)}$ except possibly some from $\tau_{r'}^{-1}(\ell)$, as required for (COV1).

We will now use $J_{r'}$ to cover the remaining $\mathcal{T}'$-important edges of $H''_\ell$. Let $J'_\ell := H''_\ell - \mathcal{F}_{\ell-1}^{(r)} - \mathcal{F}_{\ell}^{(r)}$. Let $S_{r'}^{\ast, \dagger} \subseteq (V(F))$ be such that $F(S_{r'}^{\ast, \dagger})$ is non-empty.

**Claim 4:** $J'_\ell(T)[U_T]$ is $F(S_{r'}^{\ast, \dagger})$-divisible for every $T \subseteq \mathcal{T}'$.

**Proof of claim:** Let $T \subseteq \mathcal{T}'$ and $b' \subseteq U_T$ with $|b'| \leq r - i' - 1$. We have to show that $\text{Deg}(F(S_{r'}^{\ast, \dagger})) | | J'_\ell(T)[U_T](b')|$. Note that for every $e \in J'_\ell \subseteq G^{(r)}_\ell$ containing $T$, we have $\tau_{r'}(e) = r - i'$. Thus, $J'_\ell(T)[U_T]$ is identical with $J'_\ell(T)$ except for the different vertex sets. It
is thus sufficient to show that $\text{Deg}(F(S^*_\ell))|_{|y|_1} \parallel |J'_\ell[T \cup b]|$. By Proposition 5.3, we have that $\text{Deg}(F(S^*_\ell))|_{|y|_1} = \text{Deg}(F(|y|_1|T \cup b|))$. Let $S := T|S$ and $b := b' \cup (T \setminus S)$. By assumption, $H^* \cup L^*$ is $F$-divisible with respect to $S, U$. Thus, since $S \in S, |b| \leq r - i - 1$ and $|b \setminus U_S| \geq |T \setminus S| \geq 1$, we have that $\text{Deg}(F)|_{i+|b|} \parallel (H^* \cup L^*)(S|b)$. This implies that $\text{Deg}(F)|_{i+|b|} \parallel ((H^* \cup L^*) - \mathcal{F}^{\rho(r)}(S \cup b)).$ It is thus sufficient to prove that $J'_\ell(T \cup b') = (H^* \cup L^*) - \mathcal{F}^{\rho(r)}(S \cup b)$. Clearly, $J'_\ell \subseteq H^* \cup \mathcal{F}^{\rho(r)} - \mathcal{F}^{\rho(r)}$ by definition. Conversely, observe that every $e \in (H^* \cup L^*) - \mathcal{F}^{\rho(r)}$ that contains $T \cup b'$ must belong to $J'_\ell$. Indeed, since $L^* \subseteq \mathcal{F}^{\rho(r)}$, we have $e \in H^*$, and since $e$ contains $T$, we have $\tau_r(e) \leq \ell$. Hence, $e \in H^*_\ell$ and thus $e \in J'_\ell$. This implies the claim.

Let $L'_\ell := J'_\ell \triangle J_\ell$. So $J'_\ell = J_\ell \cup L'_\ell$.

**Claim 5:** $L'_\ell \subseteq G^{\rho(r)}$ and $\Delta(L'_\ell) \leq 3\nu n$.

**Proof of claim:** Suppose, for a contradiction, that there is $e \in J'_\ell \cup J_\ell$ with $e \notin G^{\rho(r)}$. By (10.14) and (10.17), the latter implies that $e$ is $S$-important with $\tau_r(e) < \ell$ or $T'$-important with $\tau_r(e) < \ell$. However, since $J'_\ell \subseteq G^{\rho(r)}$, we must have $e \in J'_\ell - J_\ell$ and thus $e \in H'_\ell$ and $e \notin \mathcal{F}^{\rho(r)}$. In particular, $e \in H^*_\ell$. Now, if $e$ was $S$-important with $\tau_r(e) < \ell$, then $e \in H'_\ell - H_\ell \subseteq H'_\ell$. But then $e$ would be covered by $\mathcal{F}^{\rho(r)}$, a contradiction. So $e$ must be $T'$-important with $\tau_r(e) < \ell$. But since $e \in H'_\ell$, $e$ would be covered by $\mathcal{F}^\ell$ unless $\tau_r(e) = \ell$, a contradiction.

In order to see the second part, observe that

$$L'_\ell = ((H'_\ell \cup J_\ell) - \mathcal{F}^{\rho(r)}(T'_\ell - \mathcal{F}^{\rho(r)})) \triangle J_\ell \subseteq H'_\ell \cup L^*$$

since $\mathcal{F}^{\rho(r)} \cup \mathcal{F}^{\rho(r)} \subseteq H'_\ell \cup L^*$. Thus, $\Delta(L'_\ell) \leq \Delta(H'_\ell) + \Delta(L^*) \leq 3\nu n$.

Note that Claim 5 implies that $J'_\ell \subseteq G^{\rho(r)}$. Let

$$G_{\ell,\text{clean}} := G^{\rho(r)}[J'_\ell] - \mathcal{F}^{\rho(r)} \subseteq \mathcal{F}^{\rho(r)} - O^*.$$

By $(\#)_\ell$, (COV1) and Fact 5.4(i), we have that

$$\Delta(\mathcal{F}^{\rho(r)} \subseteq \mathcal{F}^{\rho(r)} - O^*) \leq (3\sqrt{\kappa}(f - r) + (2\sqrt{\kappa})(f - r) + \gamma n \leq 2\gamma n.$$

Thus, by (10.18), Claim 4 and Claim 5, $G_{\ell,\text{clean}}(T)[U_T]$ is an $F(S^*_\ell)$-divisible ($\rho_\ell, \beta^{S^*_\ell} + 1, f - i', r - i')$-supercomplex for every $T \in T'$. Moreover, whenever there are $T \in T'^{(i)}$ and $e \in G^{\rho(r)}_{\ell,\text{clean}} \subseteq G^{\rho(r)}_{\ell,\text{clean}}$ with $T \subseteq e$, then $|e \cap T| \cup T| = \tau_r(e) = \ell = |e \setminus T|$ and thus $e \setminus T \subseteq U_T$. By (I), $G_{\ell,\text{clean}} \subseteq G_{\ell}$ is $r$-exclusive with respect to $T'$, and by (a), $U^{\ell'}$ is a $(\mu, \rho_\ell, r)$-focus for $T'$. We can therefore apply the Localised cover down lemma (Lemma 10.8) along with the following objects/parameters.

This yields a $\rho_\ell^{-1/2}$-well separated $F$-packing $F^{\uparrow}_{\ell}$ in $G_{\ell,\text{clean}}$ covering all $T'$-important edges of $G^{\rho(r)}_{\ell,\text{clean}} = J'_\ell = H'_\ell \cup \mathcal{F}^{\rho(r)}(S \cup b)$. Thus $F^{\uparrow}_{\ell}$ is as required in (COV2). As observed before, this completes the proof of (\#)$_\ell$, and thus the proof of (i).

**Proof of (ii).**

Let $Y \subseteq G^{(f)}$ and $A \in [0, 1]^{(r+1) \times (f+1)}$ be such that (S1)-(S4) hold. We assume that $G^{(r)}$ is $F$-divisible with respect to $S, U$ and that $A$ is diagonal-dominant.

**Claim 6:** $G$ is $(\xi - \varepsilon, f, r)$-dense with respect to $G^{(r)} - \tau_r^{-1}(0)$.

**Proof of claim:** Let $e \in G^{(r)}$ and let $\ell' \in [r + 1]$ be such that $e \in \mathcal{P}(\ell')$. Suppose first that $\ell' \leq i$. Then no $f$-set from $\mathcal{P}(\ell')$ contains any edge from $\tau_r^{-1}(0)$ (as such an $f$-set is $S$-unimportant).
Recall from (S2) for $\mathcal{S}, \mathcal{U}, (\mathcal{P}_r, \mathcal{P}_f)$ that $G[Y]$ is $(\varepsilon, A, f, r)$-regular with respect to $(\mathcal{P}_r, \mathcal{P}_f[Y])$ and $\min^{\nu+\varepsilon} f(r) \geq \xi$. Thus, 
$$|G(r) - \tau^{-1}(0))| \geq |Y \cap \mathcal{P}_f(l')|(e) \geq (a_{f,r} - \varepsilon)n^{f-r} \geq (\xi - \varepsilon)n^{f-r}.$$ 

If $l' > i + 1$, then by (P2') in Proposition 10.12, no $f$-set from $\mathcal{P}_f(f - r + l')$ contains any edge from $\tau^{-1}(0)$. Thus, we have 
$$|G((G(r) - \tau^{-1}(0))| \geq (a_{f,r} - \varepsilon)n^{f-r} \geq (\xi - \varepsilon)n^{f-r}.$$ 

If $l' = i + 1$, then $\mathcal{P}_r(l') = \tau^{-1}(0)$ by (P2'). However, every $f$-set from $\tau^{-1}(f - r) = \mathcal{P}_f(f - r + l')$ that contains $e$ contains no other edge from $\tau^{-1}(0)$. Thus, 
$$|G((G(r) - \tau^{-1}(0))| \geq (a_{f,r} - \varepsilon)n^{f-r} \geq (\xi - \varepsilon)n^{f-r}.$$ 

By Claim 6, we can choose $H^* \subseteq G(r) - \tau^{-1}(0)$ such that (i) holds with $G$ playing the role of $\tilde{G}$. Let 
$$H_{\text{nibble}} := G(r) - H^*.$$ 

Recall that by (S2), $G[Y]$ is $(\varepsilon, A, f, r)$-regular with respect to $(\mathcal{P}_r, \mathcal{P}_f[Y])$, and (S3) implies that $G[Y]$ is $(\mu_r \xi, f + r, r)$-dense. Let 
$$G_{\text{nibble}} := (G[Y])|H_{\text{nibble}}.$$ 

Using Proposition 5.7, it is easy to see that $G_{\text{nibble}}$ is $(2r+1, A, f, r)$-regular with respect to $(\mathcal{P}_r, \mathcal{P}_f)[G_{\text{nibble}}]$. Moreover, by Proposition 5.9(ii), $G_{\text{nibble}}$ is $(\mu_r \xi/2, f + r, r)$-dense. Thus, by Lemma 10.17, there exists $Y^* \subseteq G(f)$ such that $G_{\text{nibble}}[Y^*]$ is $(\sqrt{\nu}, A, f, r)$-regular for $d := \min \{\xi \geq \xi \text{ and } (0.45\mu_r \xi/8(f + 1))^{(f+r)} \geq f + r, r\}-dense. Thus, by Lemma 6.5 there is a $\kappa$-well separated $F$-packing $F'_{\text{nibble}}$ in $G_{\text{nibble}}[Y^*]$ such that $\Delta(L_{\text{nibble}}) \leq \gamma_n$, where $L_{\text{nibble}} := G_{\text{nibble}}[Y^*][F] - F'_{\text{nibble}}$. Hence, $L_{\text{nibble}}$ is $F$-divisible with respect to $S, U$, we clearly have that $H^* \cup L_{\text{nibble}} = G(r) - F'_{\text{nibble}}$ is $F$-divisible with respect to $\mathcal{S}, \mathcal{U}$. By Fact 5.4(i), we have that $\Delta(L_{\text{nibble}}) \leq \kappa(f - r) \leq \gamma n$. Thus, by (i), there exists a $\kappa$-well separated $F$-packing $F^*$ in $G[H^* \cup L_{\text{nibble}}] = F^*_{\text{nibble}}$ which covers all edges of $L_{\text{nibble}}$, and all $S$-important edges of $H^*$ except possibly some from $\tau^{-1}(r - i)$. But then, by Fact 5.4(ii), $F_{\text{nibble}} \cup F^*$ is a $2\kappa$-well separated $F$-packing in $G$ which covers all $S$-important $r$-edges except possibly some from $\tau^{-1}(r - i)$, completing the proof.

This completes the proof of Lemma 10.24.

11. Achieving Divisibility

It remains to show that we can turn every $F$-divisible $r$-graph $G$ into an $F^*$-divisible $r$-graph $G'$ by removing a sparse $F$-decomposable subgraph of $G$, that is, to prove Lemma 9.4. Note that in Lemma 9.4, we do not need to assume that $F^*$ is weakly regular. On the other hand, our argument heavily relies on the assumption that $F^*$ is $F$-decomposable.

We first sketch the argument. Let $F^*$ be $F$-decomposable, let $b_k := \text{Deg}(F^*)_k$ and $h_k := \text{Deg}(F)_k$. Clearly, we have $h_k | b_k$. First, consider the case $k = 0$. Then $b_0 = |F^*|$ and $h_0 = |F|$. We know that $|G|$ is divisible by $h_0$. Let $0 \leq x < b_0$ be such that $|G| \equiv x \mod b_0$. Since $h_0$ divides $|G|$ and $b_0$, it follows that $x = ah_0$ for some $0 < a < b_0/h_0$. Thus, removing $a$ edge-disjoint copies of $F$ from $G$ yields an $r$-graph $G'$ such that $|G'| = |G| - ah_0 \equiv 0 \mod b_0$, as desired. This will in fact be the first step of our argument.

We then proceed by achieving $\text{Deg}(G')_1 \equiv 0 \mod b_1$. Suppose that the vertices of $G'$ are ordered $v_1, \ldots, v_n$. We will construct a degree shifter which will fix the degree of $v_1$ by allowing the degree of $v_2$ to change, whereas all other degrees are unaffected (modulo $b_1$). Step by step, we will fix all the degrees from $v_1, \ldots, v_{n-1}$. Fortunately, the degree of $v_n$ will then automatically be divisible by $b_1$. For $k > 1$, we will proceed similarly, but the procedure becomes more intricate. It is in general impossible to shift degree from one $k$-set to another one without affecting the degrees
of any other $k$-set. Roughly speaking, the degree shifter will contain a set of $2k$ special ‘root vertices’, and the degrees of precisely $2^k k$-subsets of this root set change, whereas all other $k$-degrees are unaffected (modulo $b_k$). This will allow us to fix all the degrees of $k$-sets in $G'$ except the ones inside some final $(2k - 1)$-set, where we use induction on $k$ as well. Fortunately, the remaining $k$-sets will again automatically satisfy the desired divisibility condition (cf. Lemma 11.5).

The proof of Lemma 9.4 divides into three parts. In the first subsection, we will construct the degree shifters. In the second subsection, we show on a very abstract level (without considering a particular host graph) how the shifting has to proceed in order to achieve overall divisibility. Finally, we will prove Lemma 9.4 by embedding our constructed shifters (using Lemma 5.20) according to the given shifting procedure.

11.1. Degree shifters. The aim of this subsection is to show the existence of certain $r$-graphs which we call degree shifters. They allow us to locally ‘shift’ degree among the $k$-sets of some host graph $G$.

Definition 11.1 (x-shifter). Let $1 \leq k < r$ and let $F, F^*$ be $r$-graphs. Given an $r$-graph $T_k$ and distinct vertices $x_1^0, \ldots, x_k^0, x_1^1, \ldots, x_k^1$ of $T_k$, we say that $T_k$ is an $(x_1^0, \ldots, x_k^0, x_1^1, \ldots, x_k^1)$-shifter with respect to $F, F^*$ if the following hold:

(SH1) $T_k$ has a well-separated $F$-decomposition $\mathcal{F}$ such that for all $F' \in \mathcal{F}$ and all $i \in [k]$, 
$$|V(F') \cap \{x_i^0, x_i^1\}| \leq 1;$$

(SH2) $|T_k(S)| \equiv 0 \pmod{\deg(F^*)_k}$ for all $S \subseteq V(T_k)$ with $|S| < k$;

(SH3) for all $S \in (V(T_k))$
$$|T_k(S)| \equiv \begin{cases} (-1)^{\sum_{i \in [k]} z_i} \deg(F)_k \pmod{\deg(F^*)_k} & \text{if } S = \{x_i^z : i \in [k]\}, \\ 0 \pmod{\deg(F^*)_k} & \text{otherwise.} \end{cases}$$

We will now show that such shifters exist. Ultimately, we seek to find them as rooted subgraphs in some host graph $G$. Therefore, we impose additional conditions which will allow us to apply Lemma 5.20.

Lemma 11.2. Let $1 \leq k < r$, let $F, F^*$ be $r$-graphs and suppose that $F^*$ has a 1-well separated $F$-decomposition $\mathcal{F}$. Let $f^* := |V(F^*)|$. There exists an $(x_1^0, \ldots, x_k^0, x_1^1, \ldots, x_k^1)$-shifter $T_k$ with respect to $F, F^*$ such that $T_k[X]$ is empty and $T_k$ has degeneracy at most $\left(f^* \left(\frac{r-1}{r} \right)\right)$ rooted at $X$, where $X := \{x_1^0, \ldots, x_k^0, x_1^1, \ldots, x_k^1\}$.

In order to prove Lemma 11.2, we will first prove a multigraph version (Lemma 11.4), which is more convenient for our construction. We will then recover the desired (simple) $r$-graph by applying an operation similar to the extension operator $\mathcal{V}_{(F,e_0)}$ defined in Section 8.2. The difference is that instead of extending every edge to a copy of $F$, we will consider an $F$-decomposition of the multigraph shifter and then extend every copy of $F$ in this decomposition to a copy of $F^*$ (and then delete the original multigraph).

For a word $w = w_1 \ldots w_k \in \{0, 1\}^k$, let $|w|_0$ denote the number of 0’s in $w$ and let $|w|_1$ denote the number of 1’s in $w$. Let $W_e(k)$ be the set of words $w \in \{0, 1\}^k$ with $|w|_1$ being even, and let $W_o(k)$ be the set of words $w \in \{0, 1\}^k$ with $|w|_1$ being odd.

Fact 11.3. For every $k \geq 1$, $|W_e(k)| = |W_o(k)| = 2^k-1$.

Lemma 11.4. Let $1 \leq k < r$ and let $F, F^*$ be $r$-graphs such that $F^*$ is $F$-decomposable. Let $x_1^0, \ldots, x_k^0, x_1^1, \ldots, x_k^1$ be distinct vertices. There exists a multi-$r$-graph $T_k^*$ which satisfies (SH1)–(SH3), except that $F$ does not need to be 1-well separated.

Proof. Let $S_k := (V(F^*))$. For every $S^* \in S_k$, we will construct a multi-$r$-graph $T_{k,S^*}$ such that $x_1^0, \ldots, x_k^0, x_1^1, \ldots, x_k^1 \in V(T_{k,S^*})$ and

(sh1) $T_{k,S^*}$ has an $F$-decomposition $\mathcal{F}$ such that for all $F' \in \mathcal{F}$ and all $i \in [k]$, $|V(F') \cap \{x_i^0, x_i^1\}| \leq 1$;

(sh2) $|T_{k,S^*}(S)| \equiv 0 \pmod{\deg(F^*)_k}$ for all $S \subseteq V(T_{k,S^*})$ with $|S| < k$;
Following from this, it is easy to construct $T^*_k$ by overlaying the above multi-$r$-graphs $T_{k,S^*}$. Indeed, there are integers $(a_{S^*}^i)_{S^* \in S_k}$ such that $\sum_{S^* \in S_k} a_{S^*}^i |F(S^*)| = \deg(F)_k$. Hence, there are positive integers $(a_{S^*})_{S^* \in S_k}$ such that

$$\sum_{S^* \in S_k} a_{S^*} |F(S^*)| \equiv \deg(F)_k \mod \deg(F^*)_k.$$  

Therefore, we take $T^*_k$ to be the union of $a_{S^*}$ copies of $T_{k,S^*}$ for each $S^* \in S_k$. Then $T^*_k$ has the desired properties.

Let $S^* \in S_k$. It remains to construct $T_{k,S^*}$. Let $X_0 := \{x^0_1, \ldots, x^0_k\}$ and $X_1 := \{x^1_1, \ldots, x^1_k\}$. We may assume that $V(F^*) \cap (X_0 \cup X_1) = \emptyset$. Let $F^*$ be an $F$-decomposition of $F^*$ and $F' \in F^*$. Let $X = \{x_1, \ldots, x_k\} \subseteq V(F')$ be the $k$-set which plays the role of $S^*$ in $F'$, in particular $|F'(X)| = |F(S^*)|$. We first define an auxiliary $r$-graph $T_{1,x_k}$ as follows: Let $F''$ be obtained from $F'$ by replacing $x_k$ with a new vertex $\hat{x}_k$. Then let

$$T_{1,x_k} := (F^* - F') \cup F''.$$  

Clearly, $(F^* \setminus \{F'\}) \cup \{F''\}$ is an $F$-decomposition of $T_{1,x_k}$. Moreover, observe that for every set $S \subseteq V(T_{1,x_k})$ with $|S| < r$, we have

$$|T_{1,x_k}(S)| = \begin{cases} 0 & \text{if } \{x_k, \hat{x}_k\} \subseteq S; \\
|F^*(S)| & \text{if } \{x_k, \hat{x}_k\} \cap S = \emptyset; \\
|F^*(S)| - |F'(S)| & \text{if } x_k \in S, \hat{x}_k \notin S; \\
|F''(S)| = |F'((S \setminus \{\hat{x}_k\}) \cup \{x_k\})| & \text{if } x_k \notin S, \hat{x}_k \in S. \end{cases}$$

We now overlay copies of $T_{1,x_k}$ in a suitable way in order to obtain the multi-$r$-graph $T_{k,S^*}$. The vertex set of $T_{k,S^*}$ will be

$$V(T_{k,S^*}) = (V(F^*) \setminus X) \cup X_0 \cup X_1.$$  

For every word $w = w_1 \ldots w_{k-1} \in \{0,1\}^{k-1}$, let $T_w$ be a copy of $T_{1,x_k}$, where

(a) for each $i \in [k-1]$, $x_{i}^{w_i}$ plays the role of $x_i$ (and $x_i^{1-w_i} \notin V(T_w)$);
(b) if $|w|_1$ is odd, then $x^0_{i}$ plays the role of $x_k$ and $x^1_{i}$ plays the role of $\hat{x}_k$, whereas if $|w|_1$ is even, then $x^0_{i}$ plays the role of $\hat{x}_k$ and $x^1_{i}$ plays the role of $x_k$;
(c) the vertices in $V(T_{1,x_k}) \setminus \{x_1, \ldots, x_{k-1}, x_k, \hat{x}_k\}$ keep their role. Let

$$T_{k,S^*} := \bigcup_{w \in \{0,1\}^{k-1}} T_w.$$  

(Note that if $k = 1$, then $T_{k,S^*}$ is just a copy of $T_{1,x_k}$, where $x^0_1$ plays the role of $\hat{x}_1$ and $x^1_1$ plays the role of $x_1$.) We claim that $T_{k,S^*}$ satisfies (sh1)–(sh3). Clearly, (sh1) is satisfied because each $T_w$ is a copy of $T_{1,x_k}$ which is $F$-decomposable, and for all $w \in \{0,1\}^{k-1}$ and all $i \in [k-1]$, $|V(T_w) \cap \{x^0_{i}, x^1_{i}\}| = 1$, and since $x_k \notin V(F'')$.

We will now use (11.2) in order to determine an expression for $|T_{k,S^*}(S)|$ (see (11.3)) which will imply (sh2) and (sh3). Call $S \subseteq V(T_{k,S^*})$ degenerate if $\{x_i^0, x_i^1\} \subseteq S$ for some $i \in [k]$. Clearly, if $S$ is degenerate, then $|T_w(S)| = 0$ for all $w \in \{0,1\}^{k-1}$. If $S \subseteq V(T_{k,S^*})$ is non-degenerate, define $I(S)$ as the set of all indices $i \in [k]$ such that $|S \cap \{x_i^0, x_i^1\}| = 1$, and define the ‘projection’

$$\pi(S) := (S \setminus (X_0 \cup X_1)) \cup \{x_i : i \in I(S)\}.$$  

Clearly, $\pi(S) \subseteq V(F^*)$ and $|\pi(S)| = |S|$. Note that if $S \subseteq V(T_w)$ and $k \notin I(S)$, then $S$ plays the role of $\pi(S) \subseteq V(T_{1,x_k})$ in $T_w$ by (a). For $i \in I(S)$, let $z_i(S) \in \{0,1\}$ be such that
Proof of Lemma 11.2.

As seen above, if $S$ is degenerate, then we have $|T_{k,S^*}(S)| = 0$. From now on, we assume that $S$ is non-degenerate. Let $W(S)$ be the set of words $w = w_1 \ldots w_{k-1} \in \{0,1\}^{k-1}$ such that $w_i = z_i(S)$ for all $i \in I(S) \setminus \{k\}$. Clearly, if $w \in \{0,1\}^{k-1} \setminus W(S)$, then $|T_{w}(S)| = 0$ by (a).

Suppose that $w \in W(S)$. If $k \notin I(S)$, then $S$ plays the role of $\pi(S)$ in $T_w$ and hence we have $|T_w(S)| = |T_{1,x_k}(\pi(S))| = |F^*(\pi(S))|$ by (11.2). It follows that $|T_{k,S^*}(S)| \equiv 0 \mod \text{Deg}(F^*_{|S|})$, as required.

From now on, suppose that $k \in I(S)$. Let

$$W_e(S) := \{w \in W(S) : |w|_1 + z_k(S) \text{ is even}\};$$
$$W_o(S) := \{w \in W(S) : |w|_1 + z_k(S) \text{ is odd}\}.$$

By (b), we know that $x_k^{z(S)}$ plays the role of $x_k$ in $T_w$ if $w \in W_o(S)$ and the role of $\hat{x}_k$ if $w \in W_e(S)$. Hence, if $w \in W_o(S)$ then $S$ plays the role of $\pi(S)$ in $T_w$, and if $w \in W_e(S)$, then $S$ plays the role of $(\pi(S) \setminus \{x_k\}) \cup \{\hat{x}_k\}$ in $T_w$. Thus, we have

$$|T_w(S)| = \begin{cases} [T_{1,x_k}(\pi(S))]^{(11.2)} = |F^*(\pi(S))| - |F^*(\pi(S))| & \text{if } w \in W_o(S); \\ [T_{1,x_k}(\pi(S) \setminus \{x_k\}) \cup \{\hat{x}_k\})]^{(11.2)} = |F^*(\pi(S))| & \text{if } w \in W_e(S); \\ 0 & \text{if } w \notin W(S). \end{cases}$$

It follows that

$$|T_{k,S^*}(S)| = \sum_{w \in \{0,1\}^{k-1}} |T_w(S)| \equiv (|W_e(S)| - |W_o(S)|) |F^*(\pi(S))| \mod \text{Deg}(F^*_{|S|}) .$$

Observe that

$$|W_e(S)| = |\{w' \in \{0,1\}^{k-|I(S)|} : |w'|_1 + z(S) \text{ is even}\}|;$$
$$|W_o(S)| = |\{w' \in \{0,1\}^{k-|I(S)|} : |w'|_1 + z(S) \text{ is odd}\}|.$$

Hence, if $|I(S)| < k$, then by Fact 11.3 we have $|W_e(S)| = |W_o(S)| = 2^{k-|I(S)|} - 1$. If $|I(S)| = k$, then $|W_e(S)| = 1$ if $z(S)$ is even and $|W_o(S)| = 0$ if $z(S)$ is odd, and for $W_o(S)$, the reverse holds. Altogether, this implies (11.3).

It remains to show that (11.3) implies (sh2) and (sh3). Clearly, (sh2) holds. Indeed, if $|S| < k$, then $S$ is degenerate or we have $|I(S)| < k$, and (11.3) implies that $|T_{k,S^*}(S)| \equiv 0 \mod \text{Deg}(F^*_{|S|})$.

Finally, consider $S \in \binom{V(T^*_{k,S})}{k}$. If $S$ does not have the form $\{x_i^{z_i} : i \in [k]\}$ for suitable $z_1, \ldots, z_k \in \{0,1\}$, then $S$ is degenerate or $|I(S)| < k$ and (11.3) implies that $|T_{k,S^*}(S)| \equiv 0 \mod \text{Deg}(F^*_{k})$, as required. Assume now that $S = \{x_i^{z_i} : i \in [k]\}$ for suitable $z_1, \ldots, z_k \in \{0,1\}$. Then $S$ is not degenerate, $I(S) = [k]$, $z(S) = \sum_{i \in [k]} z_i$ and $\pi(S) = \{x_1, \ldots, x_k\} = X$, in which case (11.3) implies that

$$|T_{k,S^*}(S)| \equiv (-1)^{z(S)} |F^*(X)| = (-1)^{z(S)} |F^*(S^*)| \mod \text{Deg}(F^*_{k}),$$

as required for (sh3).

Proof of Lemma 11.2. By applying Lemma 11.4 (with $x_k^0$ and $x_k^1$ swapping their roles), we can see that there exists a multi-r-graph $T^*_k$ with $x_0^0, \ldots, x_0^0, x_1^1, \ldots, x_k^1 \in V(T^*_k)$ such that the following properties hold:

- $T^*_k$ has an $F$-decomposition $\{F_1, \ldots, F_m\}$ such that for all $j \in [m]$ and all $i \in [k]$, we have $|V(F_j) \cap \{x_i^0, x_i^1\}| \leq 1;$
- $|T^*_k(S)| \equiv 0 \mod \text{Deg}(F^*_{|S|})$ for all $S \subseteq V(T^*_k)$ with $|S| < k$;
for all \( S \in \binom{V(T_k^*)}{k} \),
\[
|T_k^*(S)| = \begin{cases} 
(-1)^{\sum_{i \in [k]} \left\lceil \frac{z_i+1}{r} \right\rceil} \deg(F)_k \mod \deg(F^*)_k & \text{if } S = \{ x_i^+: i \in [k] \}, \\
0 \mod \deg(F^*)_k & \text{otherwise}.
\end{cases}
\]

Let \( f := |V(F)| \). For every \( j \in [m] \), let \( Z_j \) be a set of \( f^* - f \) new vertices, such that \( Z_j \cap Z_{j'} = \emptyset \) for all distinct \( j, j' \in [m] \) and \( Z_j \cap V(T_k^*) = \emptyset \) for all \( j \in [m] \). Now, for every \( j \in [m] \), let \( F_j^* \) be a copy of \( F^* \) on vertex set \( V(F_j) \cup Z_j \) such that \( F_j \cup \{ F_j^* \} \) is a 1-well separated \( F \)-decomposition of \( F_j^* \). In particular, we have that
\[
\begin{align*}
(a) & \quad (F_j^* - F_j)[V(F_j)] = \emptyset, \\
(b) & \quad F_j \text{ is a 1-well separated } F \text{-decomposition of } F_j^* - F_j \text{ such that for all } F' \in F_j, |V(F') \cap V(F_j)| \leq r - 1.
\end{align*}
\]

Let
\[
T_k := \bigcup_{j \in [m]} (F_j^* - F_j).
\]

We claim that \( T_k \) is the desired shifter. First, observe that \( T_k \) is a (simple) \( r \)-graph since \((F_j^* - F_j)[V(F_j)]\) is empty for every \( j \in [m] \) by (a). Moreover, since \( F_1, \ldots, F_m \) are \( r \)-disjoint by (b), Fact 5.4(iii) implies that \( F := F_1 \cup \cdots \cup F_m \) is a 1-well separated \( F \)-decomposition of \( T_k \), and for each \( j \in [m] \), all \( F' \in F_j \) and all \( i \in [k] \), we have \(|V(F') \cap \{ x_i^0, x_i^1 \}| \leq |V(F_j) \cap \{ x_i^0, x_i^1 \}| \leq 1 \). Thus, (SH1) holds.

Moreover, note that for every \( j \in [m] \), we have \(|(F_j^* - F_j)[S]| \equiv -|F_j(S)| \mod \deg(F^*)_|S| \) for all \( S \subseteq V(T_k) \) with \(|S| \leq r - 1 \). Thus,
\[
|T_k(S)| \equiv \sum_{j \in [m]} -|F_j(S)| = -|T_k^*(S)| \mod \deg(F^*)_|S|
\]
for all \( S \subseteq V(T_k) \) with \(|S| \leq r - 1 \). Hence, (SH2) clearly holds. If \( S = \{ x_i^{z_i} : i \in [k] \} \) for suitable \( z_1, \ldots, z_k \in \{ 0, 1 \} \), then
\[
|T_k(S)| \equiv -|T_k^*(S)| \equiv (-1)^{\sum_{i \in [k]} z_i} \deg(F)_k \mod \deg(F^*)_k
\]
and (SH3) holds. Thus, \( T_k \) is indeed an \((x_1^0, \ldots, x_k^0, x_1^1, \ldots, x_k^1)\)-shifter with respect to \( F, F^* \).

Finally, to see that \( T_k \) has degeneracy at most \( \binom{r}{r-1} \) rooted at \( X \), consider the vertices of \( V(T_k^*) \setminus X \) in an ordering where the vertices of \( V(T_k^*) \setminus X \) preceed all the vertices in sets \( Z_j \), for \( j \in [m] \). Note that \( T_k[V(T_k^*)] \) is empty by (a), i.e. a vertex in \( V(T_k^*) \setminus X \) has no ‘backward’ edges. Moreover, if \( z \in Z_j \) for some \( j \in [m] \), then \( |T_k(\{z\})| = |F_j^*(\{z\})| \leq \binom{r}{r-1} \).

11.2. Shifting procedure. In the previous section, we constructed degree shifters which allow us to locally change the degrees of \( k \)-sets in some host graph. We will now show how to combine these local shifts in order to transform any given \( F \)-divisible \( r \)-graph \( G \) into an \( F^* \)-divisible \( r \)-graph. It turns out to be more convenient to consider the shifting for ‘\( r \)-set functions’ rather than \( r \)-graphs. We will then recover the graph theoretical statement by considering a graph as an indicator set function (see below).

Let \( \phi : \binom{V}{r} \rightarrow \mathbb{Z} \). (Think of \( \phi \) as the multiplicity function of a multi-\( r \)-graph.) We extend \( \phi \) to \( \phi : \bigcup_{k \in [r]} \binom{V}{k} \rightarrow \mathbb{Z} \) by defining for all \( S \subseteq V \) with \(|S| = k \leq r \),
\[
(11.4) \quad \phi(S) := \sum_{S' \in \binom{V}{r}} \phi(S').
\]

Thus for all \( 0 \leq i \leq k \) and all \( S \in \binom{V}{r} \),
\[
(11.5) \quad \binom{r-i}{k-i} \phi(S) = \sum_{S' \in \binom{V}{k}} \phi(S').
\]

For \( k \in [r-1] \) and \( b_0, \ldots, b_k \in \mathbb{N} \), we say that \( \phi \) is \((b_0, \ldots, b_k)\)-divisible if \( b_{|S|} | \phi(S) \) for all \( S \subseteq V \) with \(|S| \leq k \).
If \( G \) is an \( r \)-graph with \( V(G) \subseteq V \), we define \( \mathds{1}_G : \binom{V}{r} \to \mathbb{Z} \) as

\[
\mathds{1}_G(S) := \begin{cases} 
1 & \text{if } S \in G; \\
0 & \text{if } S \notin G.
\end{cases}
\]

and extend \( \mathds{1}_G \) to \( \bigcup_{k \in [r]} \binom{V}{k} \) as in (11.4). Hence, for a set \( S \subseteq V \) with \( |S| < r \), we have \( \mathds{1}_G(S) = |G(S)| \). Thus, (11.5) corresponds to the handshaking lemma for \( r \)-graphs (cf. (5.1)). Clearly, if \( G \) and \( G' \) are edge-disjoint, then we have \( \mathds{1}_G + \mathds{1}_{G'} = \mathds{1}_{G \cup G'} \). Moreover, for an \( r \)-graph \( F \), \( G \) is \( F \)-divisible if and only if \( \mathds{1}_G \) is \( (\deg(F), \ldots, \deg(F))_{r-1} \)-divisible.

As mentioned before, our strategy is to successively fix the degrees of \( k \)-sets until we have fixed the degrees of all \( k \)-sets except possibly the degrees of those \( k \)-sets contained in some final vertex set \( K \) which is too small as to continue with the shifting. However, as the following lemma shows, divisibility is then automatically satisfied for all the \( k \)-sets lying inside \( K \). For this to work it is essential that the degrees of all \( i \)-sets for \( i < k \) are already fixed.

**Lemma 11.5.** Let \( 1 \leq k < r \) and \( b_0, \ldots, b_k \in \mathbb{N} \) be such that \( \binom{r-i}{k-1} b_i \equiv 0 \mod b_k \) for all \( i \in [k]_0 \). Let \( \phi : \binom{V}{r} \to \mathbb{Z} \) be a \( (b_0, \ldots, b_{k-1}) \)-divisible function. Suppose that there exists a subset \( K \subseteq V \) of size \( 2k - 1 \) such that if \( S \in \binom{V}{r} \) with \( \phi(S) \not\equiv 0 \mod b_k \), then \( S \subseteq K \). Then \( \phi \) is \( (b_0, \ldots, b_k) \)-divisible.

**Proof.** Let \( \mathcal{K} \) be the set of all subsets \( T'' \) of \( K \) of size less than \( k \). We first claim that for all \( T'' \in \mathcal{K} \), we have

\[
(11.6) \quad \sum_{T' \in \binom{K}{k} : T'' \subseteq T'} \phi(T') \equiv 0 \mod b_k.
\]

Indeed, suppose that \( |T''| = i < k \), then we have

\[
\sum_{T' \in \binom{K}{k} : T'' \subseteq T'} \phi(T') \equiv \sum_{T' \in \binom{K}{k} : T'' \subseteq T'} \phi(T') (11.5) \equiv \binom{r-i}{k-1} \phi(T'') \mod b_k.
\]

Since \( \phi \) is \( (b_0, \ldots, b_{k-1}) \)-divisible, we have \( \phi(T'') \equiv 0 \mod b_i \), and since \( \binom{r-i}{k-1} b_i \equiv 0 \mod b_k \), the claim follows.

Let \( T \in \binom{K}{k} \). We need to show that \( \phi(T) \equiv 0 \mod b_k \). To this end, define the function \( f : \mathcal{K} \to \mathbb{Z} \) as

\[
f(T'') := \begin{cases} 
(-1)^{|T''|} & \text{if } T'' \subseteq K \setminus T; \\
0 & \text{otherwise}.
\end{cases}
\]

We claim that for all \( T' \in \binom{K}{k} \), we have

\[
(11.7) \quad \sum_{T'' \subseteq T'} f(T'') = \begin{cases} 
1 & \text{if } T' = T; \\
0 & \text{otherwise}.
\end{cases}
\]

Indeed, let \( T' \in \binom{K}{k} \), and set \( t := |T' \setminus T| \). We then check that (using \( |K| < 2k \) in the first equality)

\[
\sum_{T'' \subseteq T'} f(T'') = \sum_{T'' \subseteq (K \setminus T) \cap T'} (-1)^{|T''|} = \sum_{j=0}^{t} (-1)^j \binom{t}{j} = \begin{cases} 
1 & \text{if } t = 0; \\
0 & \text{if } t > 0.
\end{cases}
\]

We can now conclude that

\[
\phi(T) (11.7) \sum_{T' \in \binom{K}{k}} \phi(T') \sum_{T'' \subseteq T'} f(T'') = \sum_{T'' \in \mathcal{K}} f(T'') \left( \sum_{T' \in \binom{K}{k} : T'' \subseteq T'} \phi(T') \right) (11.6) \equiv 0 \mod b_k,
\]
as desired. \( \square \)
We now define a more abstract version of degree shifters, which we call adapters. They represent the effect of shifters and will finally be replaced by shifters again.

**Definition 11.6 (\(x\)-adapter).** Let \(V\) be a vertex set and \(k, r, b_0, \ldots, b_k, h_k \in \mathbb{N} \) be such that \(k < r\) and \(h_k | b_k\). For distinct vertices \(x_1^0, \ldots, x_0^k, x_1^k, \ldots, x_k^i \) in \(V\), we say that \(\tau : \left(\begin{array}{c} r \\vspace{1mm} \\ \end{array}\right) \rightarrow \mathbb{Z}\) is an \((x_0^0, \ldots, x_0^k, x_1^0, \ldots, x_1^i)\)-adapter with respect to \((b_0, \ldots, b_k; h_k)\) if \(\tau\) is \((b_0, \ldots, b_{k-1})\)-divisible and for all \(S \in \left(\begin{array}{c} k \\vspace{1mm} \\ \end{array}\right)\),

\[
\tau(S) \equiv \begin{cases} 
-1 \sum_{i \in [k]} z_i h_k \mod b_k & \text{if } S = \{x_i^s : i \in [k]\}, \\
0 \mod b_k & \text{otherwise}.
\end{cases}
\]

Note that such an adapter \(\tau\) is \((b_0, \ldots, b_{k-1}, h_k)\)-divisible.

**Fact 11.7.** If \(T\) is an \(x\)-shifter with respect to \(F, F^*\), then \(1_T\) is an \(x\)-adapter with respect to \((\deg(F^*)_0, \ldots, \deg(F^*)_k; \deg(F)_k)\).

The following definition is crucial for the shifting procedure. Given some function \(\phi\), we intend to add adapters in order to obtain a divisible function. Every adapter is characterised by a tuple \(x\) consisting of \(2k\) distinct vertices, which tells us where to apply the adapter. All these tuples are contained within a multiset \(\Omega\), which we call a balancer. \(\Omega\) is capable of dealing with any input function \(\phi\) in the sense that there is a multisubset of \(\Omega\) which tells us where to apply the adapters in order to make \(\phi\) divisible. Moreover, as we finally want to replace the adapters by shifters (and thus embed them into some host graph), there must not be too many of them.

**Definition 11.8 (balancer).** Let \(r, k, b_0, \ldots, b_k \in \mathbb{N}\) with \(k < r\) and let \(U, V\) be sets with \(U \subseteq V\). Let \(\Omega_k\) be a multiset containing ordered tuples \(x = (x_1, \ldots, x_{2k})\), where \(x_1, \ldots, x_{2k} \in U\) are distinct. We say that \(\Omega_k\) is a \((b_0, \ldots, b_k)\)-balancer for \(V\) with uniformity \(r\) acting on \(U\) if for any \(h_k \in \mathbb{N}\) with \(h_k | b_k\), the following holds: let \(\phi : \left(\begin{array}{c} r \\vspace{1mm} \\ \end{array}\right) \rightarrow \mathbb{Z}\) be any \((b_0, \ldots, b_{k-1}, h_k)\)-divisible function such that \(S \subseteq U\) whenever \(S \in \left(\begin{array}{c} k \\vspace{1mm} \\ \end{array}\right)\) and \(\phi(S) \equiv 0 \mod b_k\). There exists a multisubset \(\Omega'\) of \(\Omega_k\) such that \(\phi + \tau_{\Omega'}\) is \((b_0, \ldots, b_k)\)-divisible, where \(\tau_{\Omega'} := \sum_{x \in \Omega'} \tau_x\) and \(\tau_x\) is any \(x\)-adapter with respect to \((b_0, \ldots, b_k; h_k)\).

For a set \(S \in \left(\begin{array}{c} k \\vspace{1mm} \\ \end{array}\right)\), let \(\deg_{\Omega_k}(S)\) be the number of \(x = (x_1, \ldots, x_{2k}) \in \Omega_k\) such that \(|S \cap \{x_i, x_{i+k}\}| = 1\) for all \(i \in [k]\). Furthermore, we denote \(\Delta(\Omega_k)\) to be the maximum value of \(\deg_{\Omega_k}(S)\) over all \(S \in \left(\begin{array}{c} k \\vspace{1mm} \\ \end{array}\right)\).

The following lemma shows that these balancers exist, i.e. that the local shifts performed by the degree shifters guaranteed by Lemma 11.2 are sufficient to obtain global divisibility (for which we apply Lemma 11.5).

**Lemma 11.9.** Let \(1 \leq k \leq r\). Let \(b_0, \ldots, b_k \in \mathbb{N}\) be such that \(\binom{r-s}{k-s} b_s \equiv 0 \mod b_k\) for all \(s \in [k]_0\). Let \(U\) be a set of \(n \geq 2k\) vertices and \(U \subseteq V\). Then there exists a \((b_0, \ldots, b_k)\)-balancer \(\Omega_k\) for \(V\) with uniformity \(r\) acting on \(U\) such that \(\Delta(\Omega_k) \leq 2k(k)!^2 b_k\).

**Proof.** We will proceed by induction on \(k\). First, consider the case when \(k = 1\). Write \(U = \{v_1, \ldots, v_n\}\). Define \(\Omega_1\) to be the multiset containing precisely \(b_1 - 1\) copies of \((v_j, v_{j+1})\) for all \(j \in [n - 1]\). Note that \(\Delta(\Omega_1) \leq 2b_1\).

We now show that \(\Omega_1\) is a \((b_0, b_1)\)-balancer for \(V\) with uniformity \(r\) acting on \(U\). Let \(\phi : \left(\begin{array}{c} r \\vspace{1mm} \\ \end{array}\right) \rightarrow \mathbb{Z}\) be \((b_0, h_1)\)-divisible for some \(h_1 \in \mathbb{N}\) with \(h_1 | b_1\), such that \(v \in U\) whenever \(v \in V\) and \(\phi(\{v\}) \equiv 0 \mod b_1\). Let \(m_0 := 0\). For each \(j \in [n - 1]\), let \(0 \leq m_j < b_1\) be such that \((m_{j-1} - m_j) h_1 \equiv \phi(\{v_j\}) \mod b_1\). Let \(\Omega' \subseteq \Omega_1\) consist of precisely \(m_j\) copies of \((v_j, v_{j+1})\) for all \(j \in [n - 1]\). Let \(\tau := \sum_{x \in \Omega'} \tau_x\), where \(\tau_x\) is an \(x\)-adapter with respect to \((b_0, b_1; h_1)\), and let \(\phi' := \phi + \tau\). Clearly, \(\phi'\) is \((b_0)\)-divisible. Note that, for all \(j \in [n - 1]\),

\[
\tau(\{v_j\}) \equiv m_j - \tau(\{v_{j-1}, v_j\})(\{v_j\}) + m_j \tau(\{v_j, v_{j+1}\})(\{v_j\}) \mod b_1
\]

\[
(11.8)
\]

implying that \(\phi'(\{v_j\}) \equiv 0 \mod b_1\) for all \(j \in [n - 1]\). Moreover, for all \(v \in V \setminus U\), we have \(\phi(\{v\}) \equiv 0 \mod b_1\) by assumption and \(\tau(\{v\}) \equiv 0 \mod b_1\) since no element of \(\Omega_1\) contains \(v\). Thus, by Lemma 11.5 (with \(\{v_n\}\) playing the role of \(K\)), \(\phi'\) is \((b_0, b_1)\)-divisible, as required.
We now assume that $k > 1$ and that the statement holds for smaller $k$. Again, write $U = \{v_1, \ldots, v_n\}$. For every $\ell \in [n]$, let $U_\ell := \{v_j : j \in [\ell]\}$. We construct $\Omega_k$ inductively. For each $\ell \in \{2k, \ldots, n\}$, we define a multiset $\Omega_{k, \ell}$ as follows. Let $\Omega_{k-1, \ell-1}$ be a $(b_1, \ldots, b_k)$-balancer for $V \setminus \{v_\ell\}$ with uniformity $r - 1$ acting on $U_{\ell-1}$ and

$$\Delta(\Omega_{k-1, \ell-1}) \leq 2^{k-1}(k-1)!^2 b_k.$$  

(Indeed, $\Omega_{k-1, \ell-1}$ exists by our induction hypothesis with $r - 1, k - 1, b_1, \ldots, b_k, U_{\ell-1}, V \setminus \{v_\ell\}$ playing the roles of $r, k, b_0, \ldots, b_k, U, V$.) For each $v = (v_j, \ldots, v_{j_{2k-2}}) \in \Omega_{k-1, \ell-1}$, let

\begin{equation}
\nu' := (v_\ell, v_{j_1}, \ldots, v_{j_{k-1}}, v_{j_k}, v_{j_{k+1}} \ldots, v_{j_{2k-2}}) \in U_\ell \times U_{\ell-1}^{2k-1},
\end{equation}

such that $j_\nu \in \{\ell - 2k + 1, \ldots, \ell\} \setminus \{j_1, \ldots, j_{2k-2}\}$ (which exists since $\ell \geq 2k$). We let $\Omega_{k, \ell} := \{\nu' : v \in \Omega_{k-1, \ell-1}\}$. Now, define

$$\Omega_k := \bigcup_{\ell = 2k}^{n} \Omega_{k, \ell}.$$

**Claim 1:** $\Delta(\Omega_k) \leq 2^k(k!)^2 b_k$

**Proof of claim:** Consider any $S \in \binom{V}{k}$. Clearly, if $S \not\subseteq U$, then $\deg_{\Omega_k}(S) = 0$, so assume that $S \subseteq U$. Let $i_0$ be the largest $i \in [n]$ such that $v_i \in S$.

First note that for all $\ell \in \{2k, \ldots, n\}$, we have

$$\deg_{\Omega_k}(S) \leq \sum_{v \in S} \deg_{\Omega_{k-1, \ell-1}}(S \setminus \{v\}) \leq k\Delta(\Omega_{k-1, \ell-1}).$$

On the other hand, we claim that if $\ell < i_0$ or $\ell \geq i_0 + 2k$, then $\deg_{\Omega_{k, \ell}}(S) = 0$. Indeed, in the first case, we have $S \not\subseteq U_\ell$ which clearly implies that $\deg_{\Omega_{k, \ell}}(S) = 0$. In the latter case, for any $v \in \Omega_{k-1, \ell-1}$, we have $j_\nu \geq \ell - 2k + 1 > i_0$ and thus $|S \cap \{v_i, v_{j_\nu}\}| = 0$, which also implies $\deg_{\Omega_{k, \ell}}(S) = 0$. Therefore,

$$\deg_{\Omega_k}(S) = \sum_{\ell = 2k}^n \deg_{\Omega_{k, \ell}}(S) \leq 2k^2\Delta(\Omega_{k-1, \ell-1}) \leq 2^k(k!)^2 b_k,$$

as required.

We now show that $\Omega_k$ is indeed a $(b_0, \ldots, b_k)$-balancer on $V$ with uniformity $r$ acting on $U$. The key to this is the following claim, which we will apply repeatedly.

**Claim 2:** Let $2k \leq \ell \leq n$. Let $\phi : \binom{V}{\ell} \to \mathbb{Z}$ be any $(b_0, \ldots, b_{\ell-1}, h_k)$-divisible function for some $h_k \in \mathbb{N}$ with $h_k \mid b_k$. Suppose that if $\phi(S) \neq 0 \mod b_k$ for some $S \in \binom{V}{k}$, then $S \subseteq U_\ell$. Then there exists $\Omega'_{k, \ell} \subseteq \Omega_{k, \ell}$ such that $\phi_{\ell-1} := \phi + \tau_{\Omega'_{k, \ell}}$ is $(b_0, \ldots, b_{\ell-1}, h_k)$-divisible and if $\phi_{\ell-1}(S) \neq 0 \mod b_k$ for some $S \in \binom{V}{k}$, then $S \subseteq U_{\ell-1}$.

(Here, $\tau_{\Omega'_{k, \ell}}$ is as in Definition 11.8, i.e. $\tau_{\Omega'_{k, \ell}} := \sum_{\nu' \in \Omega'_{k, \ell}} \tau_{\nu'}$ and $\tau_{\nu'}$ is an arbitrary $\nu'$-adapter with respect to $(b_0, \ldots, b_k; h_k)$.)

**Proof of claim:** Define $\rho : \binom{V \setminus \{v_\ell\}}{r-1} \to \mathbb{Z}$ such that for all $S \in \binom{V \setminus \{v_\ell\}}{r-1}$,

$$\rho(S) := \phi(S \cup \{v_\ell\}).$$

It is easy to check that this identity transfers to smaller sets $S$, that is, for all $S \subseteq V \setminus \{v_\ell\}$, with $|S| \leq r - 1$, we have $\rho(S) = \phi(S \cup \{v_\ell\})$, where $\rho(S) = \phi(S \cup \{v_\ell\})$ are as defined in (11.4).

Hence, since $\phi_\ell$ is $(b_0, \ldots, b_{\ell-1}, h_k)$-divisible, $\rho$ is $(b_0, \ldots, b_{\ell-1}, h_k)$-divisible. Moreover, for all $S \in \binom{V \setminus \{v_\ell\}}{k-1}$ with $\rho(S) \neq 0 \mod b_k$, we have $S \subseteq U_{\ell-1}$.

Recall that $\Omega_{k-1, \ell-1}$ is a $(b_1, \ldots, b_k)$-balancer for $V \setminus \{v_\ell\}$ with uniformity $r - 1$ acting on $U_{\ell-1}$. Thus, there exists a multiset $\Omega' \subseteq \Omega_{k-1, \ell-1}$ such that

$$\rho + \tau_{\Omega'}$$

is $(b_1, \ldots, b_k)$-divisible.

Let $\Omega'_{k, \ell} \subseteq \Omega_{k, \ell}$ be induced by $\Omega'$, that is, $\Omega'_{k, \ell} := \{\nu' : v \in \Omega'\}$ (see (11.9)). Let $\nu' \in \Omega'_{k, \ell}$ and let $\tau_{\nu'}$ be any $\nu'$-adapter with respect to $(b_0, \ldots, b_k; h_k)$. As noted after Definition 11.6,
Thus, by Claim 2, there exists \( \Omega \). This completes the proof of the claim.

By Fact 11.10, we have \( x_1, \ldots, x_{k-1}, h_k \)-divisible. Thus \( \phi \) is indeed a \((b_0, \ldots, b_{k-1}, h_k)\)-divisible function such that \( S \subseteq U \) whenever \( S \subseteq \binom{V}{k} \) and \( \phi(S) \neq 0 \mod b_k \). Let \( \phi_n := \phi \) and note that \( U = U_n \). Thus, by Claim 2, there exists \( \Omega_n \subseteq \Omega_k \) such that \( \phi_n := \phi + \tau_{\Omega_n} \) is \((b_0, \ldots, b_{k-1}, h_k)\)-divisible and if \( \phi_n(S) \neq 0 \mod b_k \) for some \( S \subseteq \binom{V}{k} \), then \( S \subseteq U_{k-1} \). Repeating this step finally yields some \( \Omega_k \subseteq \Omega_k \) such that \( \phi^* := \phi + \tau_{\Omega_k} \) is \((b_0, \ldots, b_{k-1}, h_k)\)-divisible and such that \( S \subseteq U_{2k-1} \) whenever \( S \subseteq \binom{V}{k} \) and \( \phi(S) \neq 0 \mod b_k \). By Lemma 11.5 (with \( U_{2k-1} \) playing the role of \( K \)), \( \phi^* \) is then \((b_0, \ldots, b_k)\)-divisible. Thus \( \Omega_k \) is indeed a \((b_0, \ldots, b_k)\)-balancer.

### 11.3. **Proof of Lemma 9.4.**

We now prove Lemma 9.4. For this, we consider the balancers \( \Omega_k \) guaranteed by Lemma 11.9. Recall that these consist of suitable adapters, and that Lemma 11.2 guarantees the existence of shifters corresponding to these adapters. It remains to embed these shifters in a suitable way, which is achieved via Lemma 5.20. The following fact will help us to verify the conditions of Lemma 11.9.

**Fact 11.10.** Let \( F \) be an \( r \)-graph. Then for all \( 0 \leq i \leq k < r \), we have \( \binom{r-i}{k-i} \deg(F)_i \equiv 0 \mod \deg(F)_k \).

**Proof.** Let \( S \) be any \( i \)-set in \( V(F) \). By (5.1), we have that

\[
\binom{r-i}{k-i} |F(S)| = \sum_{T \in \binom{V(F)}{k-i}} |F(T)| \equiv 0 \mod \deg(F)_k,
\]

and this implies the claim. \(\square\)

### Proof of Lemma 9.4.

Let \( x_0^i, \ldots, x_{r-1}^i, x_1^i, \ldots, x_{k-1}^i \) be distinct vertices (not in \( V(G) \)). For \( k \in [r-1] \), let \( X_k := \{x_0^i, \ldots, x_k^i, x_1^i, \ldots, x_{k-1}^i \} \). By Lemma 11.2, for every \( k \in [r-1] \), there exists an \( (x_0^i, \ldots, x_k^i, x_1^i, \ldots, x_{k-1}^i) \)-shifter \( T_k \) with respect to \( F, F^* \) such that \( T_k[X_k] \) is empty and \( T_k \) has degeneracy at most \( \binom{r-1}{k-1} \) rooted at \( X_k \). Note that (SH1) implies that

\[
\binom{r-i}{k-i} |T_k([x_0^i, x_1^i])| = 0 \text{ for all } i \in [k].
\]

We may assume that there exists \( t \geq \max_{k \in [r-1]} |V(T_k)| \) such that \( 1/n \ll \gamma \ll 1/t \ll \xi, 1/f^* \). Let \( \deg(F) = (b_0, h_1, \ldots, b_{r-1}) \) and let \( \deg(F^*) = (b_0, b_1, \ldots, b_{r-1}) \). Since \( F^* \) is \( F \)-decomposable and thus \( F \)-divisible, we have \( h_k | b_k \) for all \( k \in [r-1] \).

By Fact 11.10, we have \( \binom{r-i}{k-i} b_i \equiv 0 \mod b_k \) for all \( 0 \leq i \leq k < r \). For each \( k \in [r-1] \) with \( h_k < b_k \), we apply Lemma 11.9 to obtain a \((b_0, \ldots, b_k)\)-balancer \( \Omega_k \) for \( V(G) \) with uniformity...
For technical reasons, let $T_0$ be a copy of $F$ and let $X_0 := \emptyset$. Let $\Omega_0$ be the multiset containing $b_0/h_0$ copies of $\emptyset$, and for every $\nu \in \Omega_0$, let $\Lambda_\nu : \mathcal{X}_k \to V(G)$ be the trivial $G$-labelling of $(T_0, X_0)$. Note that $T_0$ has degeneracy at most $(r-1)$ rooted at $X_0$. Note also that $\Lambda_\nu$ does not root any set $S \subseteq V(G)$ with $|S| \in [r-1]$.

We will apply Lemma 5.20 in order to find faithful embeddings of the $T_k$ into $G$. Let $\Omega := \bigcup_{k=0}^r \Omega_k$. Let $\alpha := \gamma^{-2}/n$.

Claim 1: For every $k \in [r-1]$ and every $S \subseteq V(G)$ with $|S| \in [r-1]$, we have $|\{\nu \in \Omega_k : \Lambda_\nu \text{ roots } S\}| \leq r^{-1}\alpha n^{r-|S|}$. Moreover, $|\Omega_k| \leq r^{-1}\alpha n^r$.

Proof of claim: Let $k \in [r-1]$ and $S \subseteq V(G)$ with $|S| \in [r-1]$. Consider any $\nu = (v_1, \ldots, v_{2k}) \in \Omega_k$ and suppose that $\Lambda_\nu$ roots $S$, i.e. $S \subseteq \{v_1, \ldots, v_{2k}\}$ and $|T_k(\Lambda_\nu^{-1}(S))| > 0$. Note that if we had $\{x_0, x_1\} \subseteq \Lambda_\nu^{-1}(S)$ for some $i \in [k]$ then $|T_k(\Lambda_\nu^{-1}(S))| = 0$ by (11.11), a contradiction. We deduce that $|S \cap \{v_i, v_{i+k}\}| \leq 1$ for all $i \in [k]$, in particular $|S| \leq k$. Thus there exists $S' \supseteq S$ with $|S'| = k$ and such that $|S' \cap \{v_i, v_{i+k}\}| = 1$ for all $i \in [k]$. However, there are at most $n^{k-|S|}$ sets $S'$ with $|S'| = k$ and $S' \supseteq S$, and for each such $S'$, the number of $\nu = (v_1, \ldots, v_{2k}) \in \Omega_k$ with $|S' \cap \{v_i, v_{i+k}\}| = 1$ for all $i \in [k]$ is at most $\Delta(\Omega_k)$. Thus, $|\{\nu \in \Omega_k : \Lambda_\nu \text{ roots } S\}| \leq n^{k-|S|} \Delta(\Omega_k) \leq n^{r-1-|S|} 2^{k(k-1)/2} \leq r^{-1}\alpha n^{r-|S|}$. Similarly, we have $|\Omega_k| \leq n^k \Delta(\Omega_k) \leq r^{-1}\alpha n^r$.

Claim 1 implies that for every $S \subseteq V(G)$ with $|S| \in [r-1]$, we have

$$|\{\nu \in \Omega : \Lambda_\nu \text{ roots } S\}| \leq \alpha n^{r-|S|} - 1,$$

and we have $|\Omega| \leq b_0/h_0 + \sum_{k=1}^r |\Omega_k| \leq \alpha n^r$. Therefore, by Lemma 5.20, for every $k \in [r-1]_0$ and every $\nu \in \Omega_k$, there exists a $\Lambda_\nu$-faithful embedding $\phi_\nu$ of $(T_k, X_k)$ into $G$, such that, letting $T_\nu := \phi_\nu(T_k)$, the following hold:

(a) for all distinct $\nu_1, \nu_2 \in \Omega$, the hulls of $(T_{\nu_1}, \text{Im}(\Lambda_{\nu_1}))$ and $(T_{\nu_2}, \text{Im}(\Lambda_{\nu_2}))$ are edge-disjoint;
(b) for all $\nu \in \Omega$ and $e \in O$ with $e \subseteq V(T_\nu)$, we have $e \subseteq \text{Im}(\Lambda_\nu)$;
(c) $\Delta(\bigcup_{\nu \in \Omega} T_\nu) \leq \alpha n^{(2-r)}$.

Note that by (a), all the graphs $T_\nu$ are edge-disjoint. Let

$$D := \bigcup_{\nu \in \Omega} T_\nu.$$

By (c), we have $\Delta(D) \leq \gamma^{-2}$. We will now show that $D$ is as desired.

For every $k \in [r-1]$ and $\nu \in \Omega_k$, we have that $T_\nu$ is a $\nu$-shifter with respect to $F, F^*$ by definition of $\Lambda_\nu$ and since $\phi_\nu$ is $\Lambda_\nu$-faithful. Thus, by Fact 11.7,

(11.12) $1_{T_\nu}$ is a $\nu$-adapter with respect to $(b_0, \ldots, b_k; h_k)$.

Claim 2: For every $\Omega' \subseteq \Omega$, $\bigcup_{\nu \in \Omega'} T_\nu$ has a 1-well separated $F$-decomposition $F$ such that $F \leq (r+1)$ and $O$ are edge-disjoint.

Proof of claim: Clearly, for every $\nu \in \Omega_0$, $T_\nu$ is a copy of $F$ and thus has a 1-well separated $F$-decomposition $F_\nu = \{T_\nu\}$. Moreover, for each $k \in [r-1]$ and all $\nu = (v_1, \ldots, v_{2k}) \in \Omega_k$, $T_\nu$ has a 1-well separated $F$-decomposition $F_\nu$ by (SH1) such that for all $F' \in F_\nu$ and all $i \in [k]$, $|V(F') \cap \{v_i, v_{i+k}\}| \leq 1$.

In order to prove the claim, it is thus sufficient to show that for all distinct $\nu_1, \nu_2 \in \Omega, \mathcal{F}_{\nu_1}$ and $\mathcal{F}_{\nu_2}$ are $r$-disjoint (implying that $F := \bigcup_{\nu \in \Omega'} F_\nu$ is 1-well separated by Fact 5.4(iii)) and that for every $\nu \in \Omega, F_{\nu} \leq (r+1)$ and $O$ are edge-disjoint.

To this end, we first show that for every $\nu \in \Omega$ and $F' \in F_\nu$, we have that $|V(F') \cap \text{Im}(\Lambda_\nu)| < r$ and every $e \in (V(F'))^r$ belongs to the hull of $(T_\nu, \text{Im}(\Lambda_\nu))$. If $\nu \in \Omega_0$, this is clear since $\text{Im}(\Lambda_\nu) = \emptyset$ and $F' = T_\nu$, so suppose that $\nu = (v_1, \ldots, v_{2k}) \in \Omega_k$ for some $k \in [r-1]$. (In particular, $h_k < b_k$.) By the above, we have $|V(F') \cap \{v_i, v_{i+k}\}| \leq 1$ for all $i \in [k]$. In particular, $|V(F') \cap \text{Im}(\Lambda_\nu)| \leq k < r$, as desired. Moreover, suppose that $e \in (V(F'))^r$. If $e \cap \text{Im}(\Lambda_\nu) = \emptyset$, then $e$ belongs
to the hull of \((T_v, \text{Im}(\Lambda_v))\), so suppose further that \(S := e \cap \text{Im}(\Lambda_v)\) is not empty. Clearly, 
\(|S \cap \{v_i, v_{i+k}\}| \leq |V(F') \cap \{v_i, v_{i+k}\}| \leq 1\) for all \(i \in [k]\). Thus, there exists \(S' \supset S\) with 
\(|S'| = k\) and \(|S' \cap \{v_i, v_{i+k}\}| = 1\) for all \(i \in [k]\). By \((\text{SH3})\) (and since \(h_k < b_k\)), we have that 
\(|T_v(S')| > 0\), which clearly implies that \(|T_v(S)| > 0\). Thus, \(e \cap \text{Im}(\Lambda_v) = S\) is a root of 
\((T_v, \text{Im}(\Lambda_v))\) and therefore \(e\) belongs to the hull of \((T_v, \text{Im}(\Lambda_v))\).

Now, consider distinct \(v_1, v_2 \in \Omega\) and suppose, for a contradiction, that there is 
e \in \binom{V(G)}{r}
such that \(e \subseteq V(F') \cap V(F'')\) for some \(F' \notin \mathcal{F}_v\) and \(F'' \notin \mathcal{F}_{v_2}\). But by the above, \(e\) belongs to the hulls of both 
\((T_{v_1}, \text{Im}(\Lambda_{v_1}))\) and \((T_{v_2}, \text{Im}(\Lambda_{v_2}))\), a contradiction to \((a)\).

Finally, consider \(v \in \Omega\) and \(e \in O\). We claim that \(e \notin \mathcal{F}_v^{(r+1)}\). Let \(F' \notin \mathcal{F}_v\) and suppose, for a contradiction, that \(e \subseteq V(F')\). By \((b)\), we have \(e \subseteq \text{Im}(\Lambda_v)\). On the other hand, by the above, we have \(|V(F') \cap \text{Im}(\Lambda_v)| < r\), a contradiction.

Clearly, \(D\) is \(F\)-divisible by Claim 2. We will now show that for every \(F\)-divisible \(r\)-graph \(H\) on \(V(G)\) which is edge-disjoint from \(D\), there exists a subgraph \(D^* \subseteq D\) such that \(H \cup D^*\) is \(F\)-divisible and \(D - D^*\) has a 1-separated \(F\)-decomposition \(\mathcal{F}\) such that \(\mathcal{F}^{(r+1)}\) and \(O\) are edge-disjoint.

Let \(H\) be any \(F\)-divisible \(r\)-graph on \(V(G)\) which is edge-disjoint from \(D\). We will inductively prove that the following holds for all \(k \in [r-1]_0\):

**SHIFT** \(k\) there exists \(\Omega_k^* \subseteq \Omega_0 \cup \cdots \cup \Omega_k\) such that \(\mathbb{1}_{H \cup \cup \Omega_k^*} = (b_0, \ldots, b_k)\)-divisible, where \(D_k^* := \bigcup_{v \in \Omega_k^*} T_v\).

We first establish \(\text{SHIFT}_0\). Since \(H\) is \(F\)-divisible, we have \(|H| \equiv 0 \mod h_0\). Since \(h_0 \mid b_0\), there exists some \(0 \leq a < b_0/h_0\) such that \(|H| \equiv ah_0 \mod b_0\). Let \(\Omega_0^*\) be the multisubset of \(\Omega_0\) consisting of \(b_0/h_0 - a\) copies of \(0\). Let \(D_0^* := \bigcup_{v \in \Omega_0^*} T_v\). Hence, \(D_0^*\) is the edge-disjoint union of \(b_0/h_0 - a\) copies of \(F\). We thus have \(|H \cup D_0^*| \equiv ah_0 + |F|(b_0/h_0 - a) \equiv ah_0 + b_0 - ah_0 \equiv 0 \mod b_0\). Therefore, \(\mathbb{1}_{H \cup D_0^*}\) is \((b_0)\)-divisible, as required.

Suppose now that \(\text{SHIFT}_{k-1}\) holds for some \(k \in [r-1]\), that is, there is \(\Omega_{k-1}^* \subseteq \Omega_0 \cup \cdots \cup \Omega_{k-1}\) such that \(\mathbb{1}_{H \cup \cup \Omega_{k-1}^*} = (b_0, \ldots, b_{k-1})\)-divisible, where \(D_{k-1}^* := \bigcup_{v \in \Omega_{k-1}^*} T_v\). Note that \(D_{k-1}^*\) is \(F\)-divisible by Claim 2. Thus, since both \(H\) and \(D_{k-1}^*\) are \(F\)-divisible, we have \(\mathbb{1}_{H \cup D_{k-1}^*} = \mathbb{1}_{H \cup \cup (b_0, \ldots, b_{k-1})}(S) \equiv 0 \mod h_k\) for all \(S \in \binom{V(G)}{k}\). Hence, \(\mathbb{1}_{H \cup D_{k-1}^*}\) and \(\mathbb{1}_{H \cup \cup \Omega_k^*}\) are \((b_0, \ldots, b_k)\)-divisible. Thus, if \(h_k = b_k\), then \(\mathbb{1}_{H \cup D_{k-1}^*} = (b_0, \ldots, b_k)\)-divisible and we let \(\Omega_k^* := \emptyset\). Now, assume that \(h_k < b_k\). Recall that \(\Omega_k\) is a \((b_0, \ldots, b_k)\)-balancer and that \(h_k \mid b_k\). Thus, there exists a multisubset \(\Omega_k^*\) of \(\Omega_k\) such that the function \(\mathbb{1}_{H \cup D_{k-1}^*} + \sum_{v \in \Omega_k^*} \tau_v\) is \((b_0, \ldots, b_k)\)-divisible, where \(\tau_v\) is any \(v\)-adapter with respect to \((b_0, \ldots, b_k; h_k)\). Recall that by (11.12) we can take \(\tau_v = \mathbb{1}_{T_v}\). In both cases, let

\[
\Omega_k^* := \Omega_{k-1}^* \cup \Omega_k^* \subseteq \Omega_0 \cup \cdots \cup \Omega_k;
\]

\[
D_k^* := \bigcup_{v \in \Omega_k^*} T_v;
\]

\[
D_{k-1}^* := \bigcup_{v \in \Omega_{k-1}^*} T_v = D_{k-1}^* \cup D_k^*.
\]

Thus, \(\sum_{v \in \Omega_k^*} \tau_v = \mathbb{1}_{D_k^*}\) and hence \(\mathbb{1}_{H \cup D_k^*} = \mathbb{1}_{H \cup D_{k-1}^*} + \mathbb{1}_{D_k^*}\) is \((b_0, \ldots, b_k)\)-divisible, as required.

Finally, \(\text{SHIFT}_{r-1}\) implies that there exists \(\Omega_{r-1}^* \subseteq \Omega\) such that \(\mathbb{1}_{H \cup D^*}\) is \((b_0, \ldots, b_{r-1})\)-divisible, where \(D^* := \bigcup_{v \in \Omega_{r-1}^*} T_v\). Clearly, \(D^* \subseteq D\), and we have that \(H \cup D^*\) is \(F^*\)-divisible. Finally, by Claim 2,

\[D - D^* = \bigcup_{v \in \Omega_{r-1}^*} T_v\]

has a 1-separated \(F\)-decomposition \(\mathcal{F}\) such that \(\mathcal{F}^{(r+1)}\) and \(O\) are edge-disjoint, completing the proof. □
12. Recent developments

Since the initial submission of the current manuscript, there has been the following closely related work: firstly, for a short expository paper which demonstrates the iterative absorption method with the example of triangle decompositions, see [5].

The main result of this paper (the existence of $F$-decompositions of divisible typical hypergraphs) has been used recently by Glock, Joos, Kühn and Osthus [18] to settle a long-standing conjecture of Chung, Diaconis and Graham on the existence of universal cycles.

Amongst others, Keevash [25] proved results on the existence of resolvable designs, of designs in a partite setting as well as $F$-designs.
