ARBITRARY ORIENTATIONS OF HAMILTON CYCLES IN DIRECTED GRAPHS OF LARGE MINIMUM DEGREE

LOUIS DEBIASIO AND ANDREW TREGLOWN

ABSTRACT. In 1960, Ghouila-Houri proved that every strongly connected directed graph G on n vertices with minimum degree at least n contains a directed Hamilton cycle. We asymptotically generalize this result by proving the following: every directed graph G on n vertices with minimum degree at least (1 + o(1))n contains every orientation of a Hamilton cycle, except for the directed Hamilton cycle in the case when G is not strongly connected. In fact, this minimum degree condition forces every orientation of a cycle in G of every possible length, other than perhaps the directed cycles.

1. INTRODUCTION

1.1. Hamilton cycles in directed graphs. In this paper we give an asymptotic generalization of one of the cornerstone results in the study of directed graphs, Ghouila-Houri's theorem [8]. Throughout, the *digraphs* we consider do not have loops and we allow at most one edge in each direction between any pair of vertices. The *minimum degree* $\delta(G)$ of a digraph G is the minimum number of edges incident to a vertex in G. A *directed Hamilton cycle* in an *n*-vertex digraph is a cycle $(v_1, v_2, \ldots, v_n, v_{n+1} = v_1)$ in which every edge $v_i v_{i+1}$ $(i \in [n])$ is oriented from v_i to v_{i+1} . The notion of a *directed Hamilton path* is defined analogously.

Theorem 1.1 (Ghouila-Houri [8]). If G is a strongly connected digraph on $n \ge 2$ vertices with $\delta(G) \ge n$, then G contains a directed Hamilton cycle.

Ghouila-Houri [8] also determined the minimum degree threshold for forcing a directed Hamilton path.

Corollary 1.2 (Ghouila-Houri [8]). If G is digraph on $n \ge 2$ vertices with $\delta(G) \ge n-1$, then G contains a directed Hamilton path.

Note that the bounds on $\delta(G)$ in Theorem 1.1 and Corollary 1.2 are tight as witnessed by the usual examples of a complete bipartite digraph with parts of sizes $\lceil \frac{n}{2} \rceil - 1$ and $\lfloor \frac{n}{2} \rfloor + 1$, and the disjoint union of two complete digraphs of sizes $\lfloor \frac{n}{2} \rfloor$ and $\lceil \frac{n}{2} \rceil$, respectively. Moreover, one cannot omit the strong connectivity condition in Theorem 1.1 as there are *n*-vertex digraphs *G* with $\delta(G) = \lfloor \frac{3n}{2} \rfloor - 2$ which are not strongly connected and thus do not contain a directed Hamilton cycle.

As discussed further below, there has been significant interest in considering other orientations of Hamilton cycles in digraphs. The main result of this paper is the following asymptotic generalization of Theorem 1.1.

Theorem 1.3. For all $\eta > 0$, there exists $n_0 \in \mathbb{N}$ such that if G is a digraph on $n \ge n_0$ vertices with $\delta(G) \ge (1+\eta)n$, then G contains every orientation of a Hamilton cycle, except for the directed Hamilton cycle in the case when G is not strongly connected.

Theorem 1.3 yields the following simple consequence.

Corollary 1.4. For all $\eta > 0$, there exists $n_0 \in \mathbb{N}$ such that if G is a digraph on $n \ge n_0$ vertices with $\delta(G) \ge (1 + \eta)n$, then G contains every orientation of a Hamilton path.

Note that the minimum degree conditions in Theorem 1.3 and Corollary 1.4 are asymptotically tight as the examples given after Corollary 1.2 do not contain a Hamilton cycle (resp. path) of any orientation.

The study of Hamiltonicity in digraphs has a rich history and, as we will now discuss, Theorem 1.3 can be viewed as an asymptotic generalization of a couple of research strands in this area. For a wider survey on Hamilton cycles in digraphs, see [14].

Hamilton cycles and paths have been well-studied in *tournaments* (i.e., orientations of complete graphs). A simple argument of Rédei [17] shows that every tournament contains a directed Hamilton path. Motivated by this, in 1971 Grünbaum [10] proved that, other than three small exceptional tournaments, every tournament contains an *anti-directed* Hamilton path.¹ Rosenfeld [18] provided a short proof of Grünbaum's theorem, and also conjectured that every sufficiently large tournament contains every orientation of a Hamilton path. More than a decade later, Thomason [21] resolved Rosenfeld's conjecture. Finally, Havet and Thomassé [13] strenghtened this result, proving that, other than Grünbaum's [10] three exceptional tournaments, every tournament contains every orientation of a Hamilton path.

A classical result of Camion [5] states that a tournament contains a directed Hamilton cycle if and only if it is strongly connected. Thomassen [22] (for even $n \ge 50$) and Rosenfeld [19] (for even $n \ge 28$) proved that every *n*-vertex tournament contains an anti-directed Hamilton cycle. The latter also conjectured that every sufficiently large tournament contains every orientation of a Hamilton cycle (except perhaps the directed Hamilton cycle). After various partial results, this conjecture was proven for all tournaments on at least 68 vertices by Havet [12].

These results therefore provide a natural class of *n*-vertex digraphs G with $\delta(G) = n - 1$ that contain every orientation of a Hamilton path and Hamilton cycle (except perhaps the directed Hamilton cycle). On the other hand, Theorem 1.3 and Corollary 1.4 show that analogues of these statements hold for *all* sufficiently large digraphs at the expense of a slightly larger minimum degree condition. It would be interesting to obtain results that unify these two settings. For example, it may be the case that every sufficiently large *n*-vertex digraph with $\delta(G) \ge n - 1$ contains every orientation of a Hamilton path. This and related questions are discussed in Section 4.

¹A digraph is *anti-directed* if it does not contain a directed path on 2 edges.

Seeking to generalize Rosenfeld's [19] and Thomassen's [22] work on tournaments, in 1980 Grant [9] asked whether every even order *n*-vertex digraph G with $\delta(G) \ge n-1$ contains an anti-directed Hamilton cycle. However, Cai [4] produced an example of an *n*-vertex digraph G with $\delta(G) = n$ that does not contain an anti-directed Hamilton cycle, for every even $n \in \mathbb{N}$. This led the first author and Molla [7, Conjecture 1.7] to refine the conjecture Grant [9] hinted at: every even order *n*-vertex digraph G with $\delta(G) \ge n+1$ contains an anti-directed Hamilton cycle. Thus, Theorem 1.3 asymptotically resolves this conjecture.

There has also been interest in the minimum semi-degree threshold for forcing a given orientation of a Hamilton cycle in a digraph. Given a digraph G, its minimum semidegree $\delta^0(G)$ is the minimum of all the in- and outdegrees of the vertices in G. Ghoulia-Houri's theorem implies that every *n*-vertex digraph G with $\delta^0(G) \ge n/2$ contains a directed Hamilton cycle; indeed, such a digraph must be strongly connected. Moreover, the bound on $\delta^0(G)$ is sharp. Grant [9] gave a minimum semi-degree condition for forcing an antidirected Hamilton cycle. After a few further partial results [3, 11, 16], the first author and Molla [7] proved the following: every sufficiently large even order *n*-vertex digraph G with $\delta^0(G) \ge n/2 + 1$ contains an anti-directed Hamilton cycle; in fact, provided G is not one of two extremal examples, a minimum semi-degree of $\delta^0(G) \ge n/2$ suffices here.

Moving beyond anti-directed Hamilton cycles, we now have a complete picture of the minimum semi-degree threshold for forcing an arbitrary orientation of a Hamilton cycle. In 1995, Häggkvist and Thomason [11] proved that every sufficiently large *n*-vertex digraph G with $\delta^0(G) \ge n/2 + n^{5/6}$ contains *every* orientation of a Hamilton cycle. Twenty years later, DeBiasio, Kühn, Molla, Osthus and Taylor [6] provided the following sharp version of this result.

Theorem 1.5 (DeBiasio, Kühn, Molla, Osthus and Taylor [6]). There exists $n_0 \in \mathbb{N}$ such that for all $n \geq n_0$, if G is an n-vertex digraph with $\delta^0(G) \geq n/2$, then G contains every orientation of a Hamilton cycle that is not anti-directed.

Note that since $\delta(G) \ge 2\delta^0(G)$, Theorem 1.3 asymptotically generalizes Theorem 1.5. It would be interesting (though likely very challenging) to prove a sharp version of Theorem 1.3 á la Theorem 1.5; this is discussed further in Section 4.

1.2. **Pancylicity.** Our work also has implications to cycles of shorter length. An oriented graph is a digraph with at most one edge between any pair of vertices. An oriented cycle (resp. oriented path) is an oriented graph whose underlying graph is a cycle (resp. path). A directed cycle (resp. directed path) is an oriented cycle (resp. path) in which all edges are oriented in the same direction. The following result is a straightforward consequence of Theorem 1.3, a lemma of Taylor [20], and a couple of our auxiliary results. We defer its proof to the appendix.

Theorem 1.6. For all $k \in \mathbb{N}$ and $\gamma > 0$, there exists $n_0 \in \mathbb{N}$ such that the following holds. If G is a digraph on $n \ge n_0$ vertices with $\delta(G) \ge (1 + \frac{1}{k+1} + \gamma)n$, then G contains every oriented cycle on at most n vertices, except for perhaps the directed cycles on more than $\lceil \frac{n}{k} \rceil$ vertices. Moreover, if G is a digraph on $n \ge 2$ vertices with $\delta(G) \ge \lfloor \frac{3n}{2} \rfloor - 1$, then G contains every oriented cycle of every possible length. Note that the moreover part of Theorem 1.6 is actually a simple consequence of a generalization [1] of Bondy's pancyclicity theorem [2]. Theorem 1.6 immediately implies the following pancyclicity-type extension of Theorem 1.3.

Corollary 1.7. For all $\eta > 0$, there exists $n_0 \in \mathbb{N}$ such that if G is a digraph on $n \ge n_0$ vertices with $\delta(G) \ge (1 + \eta)n$, then G contains every oriented cycle on at most n vertices, except perhaps the directed cycles.

Note that Theorem 1.6 (including the moreover part) is best-possible in a strong sense. Indeed, let $k, n \in \mathbb{N}$ with $n \geq k + 1$. Consider the *n*-vertex digraph G_1 obtained from the transitive tournament T on k+1 vertices by blowing-up and replacing each vertex of T with a complete digraph on $\lceil \frac{n}{k+1} \rceil$ or $\lfloor \frac{n}{k+1} \rfloor$ vertices. Now we have $\delta(G_1) = n + \lfloor \frac{n}{k+1} \rfloor - 2$ and G_1 contains no directed cycle of length more than $\lceil \frac{n}{k+1} \rceil$. In particular, having $\delta(G)$ almost $(1 + \frac{1}{k+1})n$ does not guarantee directed cycles of length more than $\lceil \frac{n}{k+1} \rceil$; however, as soon as $\delta(G)$ is somewhat bigger than $(1 + \frac{1}{k+1})n$, Theorem 1.6 tells us that G in fact contains the minimum degree threshold for forcing a directed cycle of a given length in an *n*-vertex digraph:

Corollary 1.8. For any $k \in \mathbb{N}$ and any $\gamma > 0$, there exists $n_0 \in \mathbb{N}$ such that the following holds. Suppose that $n \ge n_0$ and let C be a directed cycle of length $\lceil \frac{n}{k+1} \rceil < |C| \le \lceil \frac{n}{k} \rceil$. If G is a digraph on $n \ge n_0$ vertices with $\delta(G) \ge (1 + \frac{1}{k+1} + \gamma)n$, then G contains C. On the other hand, for every $n \ge k+1$ there is an n-vertex digraph G_1 with $\delta(G_1) = n + \lfloor \frac{n}{k+1} \rfloor - 2$ that does not contain C.

1.3. **Directed 2-factors.** Recall that the moreover part of Theorem 1.6 implies that, without the assumption of strong connectivity, the minimum degree threshold for forcing a directed Hamilton cycle in an *n*-vertex digraph G is $n + \lfloor \frac{n}{2} \rfloor - 1$. The following observation generalizes this fact. Note that a *directed 2-factor* in a digraph G is a collection of vertex-disjoint directed cycles that together cover all vertices in G.

Observation 1.9. Given any $k \in \mathbb{N}$, if G is a digraph on $n \geq 2(k+1)$ vertices with $\delta(G) \geq n + \lfloor \frac{n}{k+1} \rfloor - 1$, then every strongly connected component H of G has more than $\lfloor \frac{n}{k+1} \rfloor \geq 2$ vertices and satisfies $\delta(H) \geq |V(H)| + \lfloor \frac{n}{k+1} \rfloor - 1$. Consequently, Theorem 1.1 implies that G contains a directed 2-factor with at most k cycles.

Note that the minimum degree condition in Observation 1.9 is tight as witnessed by the digraph G_1 defined after Corollary 1.7.

Organization of the paper. In Section 2 we state and prove one of our key auxiliary results, Proposition 2.1, which essentially is a 'robust' version of Observation 1.9. In Section 3 we then show that the structure obtained from Proposition 2.1 allows one to prove Theorem 1.3. In Section 4, we end the paper with a few concluding remarks and open questions. Note that we defer the proof Theorem 1.6, as well as Theorem 3.5, to the appendix.

Notation. Throughout, \mathbb{N} denotes the set of positive integers (i.e., it does not contain 0).

Let G be a digraph. We define |G| := |V(G)| and e(G) := |E(G)|. Given $x \in V(G)$, we write $N_G^+(x)$ for the *out-neighborhood of* x in G and write $N_G^-(x)$ for the *in-neighborhood*

of x in G. Thus, $|N_G^+(x)| = d_G^+(x)$ and $|N_G^-(x)| = d_G^-(x)$. Given $Y \subseteq V(G)$ we define $N_G^+(x,Y) := N_G^+(x) \cap Y$ and $N_G^-(x,Y) := N_G^-(x) \cap Y$. Set $d_G^+(x,Y) := |N_G^+(x,Y)|$ and $d_G^-(x,Y) := |N_G^-(x,Y)|$, and let $d_G(x,Y) := d_G^+(x,Y) + d_G^-(x,Y)$. We define $d_G(x) := d_G(x,V(G))$.

Given distinct $x, y \in V(G)$, we write xy for the edge directed from x to y in G; so xy and yx are different edges. We say that x sends a *double edge* to y in G if $xy, yx \in E(G)$.

Given subsets $A, B \subseteq V(G)$ (not-necessarily disjoint), let $E_G^+(A, B)$ be the set of all $xy \in E(G)$ such that $x \in A$ and $y \in B$. We set $E_G^-(A, B) := E_G^+(B, A)$ and let $E_G(X,Y) := E_G^+(X,Y) \cup E_G^-(X,Y)$. Let $e_G^+(X,Y) := |E_G^+(X,Y)|, e_G^-(X,Y) := |E_G^-(X,Y)|$, and $e_G(X,Y) = |E_G(X,Y)|$.

Given $X \subseteq V(G)$, we write G[X] for the subdigraph of G induced by X. We write $G \setminus X$ for the subdigraph of G induced by $V(G) \setminus X$.

Given a digraph G, a sink is a vertex of out-degree 0 and a source is a vertex of in-degree 0. Given an oriented cycle C, a vertex $v \in V(C)$ is a switch if it is either a source or a sink in C. A digraph is strongly connected if, for every ordered pair of distinct vertices $x, y \in V(G)$, there is a directed path from x to y in G.

When we state that a digraph G contains every orientation of a Hamilton cycle, we mean it contains every oriented cycle on |G| vertices.

Throughout the paper, we omit all floor and ceiling signs whenever these are not crucial. The constants in the hierarchies used to state our results are chosen from right to left. For example, if we claim that a result holds whenever $0 < a \ll b \ll c \leq 1$, then there are non-decreasing functions $f: (0,1] \rightarrow (0,1]$ and $g: (0,1] \rightarrow (0,1]$ such that the result holds for all $0 < a, b, c \leq 1$ with $b \leq f(c)$ and $a \leq g(b)$. Note that $a \ll b$ implies that we may assume in the proof that, e.g., a < b or $a < b^2$.

2. Partitioning into robust expanders

In this section we will make use of the concept of *robust expansion*, a notion introduced by Kühn, Osthus and Treglown [15] that has found applications to a range of graph embedding problems.

Let $0 < \nu \leq \tau < 1/2$ and let G be a digraph on n vertices. For $S \subseteq V(G)$, define $RN_{\nu}^{+}(S) := \{v \in V(G) : d_{G}^{-}(v,S) \geq \nu n\}$ to be the ν -robust out-neighborhood of S. We say that G is a robust (ν, τ) -outexpander if $|RN_{\nu}^{+}(S)| \geq |S| + \nu n$ for all $S \subseteq V(G)$ with $\tau n \leq |S| \leq (1 - \tau)n$.

The following structural result can be viewed as a robust version of Observation 1.9.

Proposition 2.1. Let $k \in \mathbb{N}$ and let $0 < 1/n_0 \ll \nu \ll \tau \ll \alpha \ll \zeta \ll 1/k$. If G is a digraph on $n \ge n_0$ vertices with $\delta(G) \ge (1 + \frac{1}{k+1} + \zeta)n$, then there exists a partition $\{V_1, \ldots, V_t\}$ of V(G) such that:

- (i) for all $i \in [t]$, $|V_i| \ge (\frac{1}{k+1} + \frac{\zeta}{2})n$, and consequently $t \le k$;
- (ii) for all $i \in [t]$, $G[V_i]$ is a robust (ν, τ) -outexpander with $\delta(G[V_i]) \ge (1 + \frac{1}{k+1} + \frac{\zeta}{2})|V_i|$;
- (iii) if $t \ge 2$, then for all $1 \le i < j \le t$, $e_G^-(V_i, V_j) > \frac{n^2}{(k+1)^2}$;
- (iv) if $t \ge 2$, then $\sum_{1 \le i < j \le t} e_G^+(V_i, V_j) \le \alpha \sum_{1 \le i < j \le t} |V_i| |V_j| \le \alpha n^2$.

Note that Proposition 2.1 implies that an *n*-vertex digraph G with $\delta(G) > (1 + \frac{1}{k+1} + o(1))n$ is either a robust outexpander (if t = 1) or has structure resembling that of the example described after Observation 1.9. More precisely, if $t \ge 2$ in Proposition 2.1, the vertex classes V_i are of reasonable size and induce robust outexpanders of large minimum degree (rather than complete digraphs). Further, the edges between vertex classes are oriented approximately as in the blow-up of a transitive tournament.

Roughly speaking, Kühn, Osthus and Treglown [15] proved that if a sufficiently large digraph G is a robust outexpander with linear minimum semi-degree, then G contains a directed Hamilton cycle. Moreover, Taylor [20] proved that such a digraph G actually contains every orientation of a Hamilton cycle (see Theorem 3.4 in Section 3).

This latter result is thus very useful when combined with Proposition 2.1. Indeed, given a digraph as in Theorem 1.3, one may apply Proposition 2.1 (with $k \in \mathbb{N}$ chosen so that $1/(k+1) \leq \eta/2$ say) to obtain the partition $\{V_1, \ldots, V_t\}$ of V(G). Given an arbitrary orientation C of an *n*-vertex cycle, Taylor's theorem allows one to find a segment of C in each $G[V_i]$ covering all of V_i . The challenge therefore is to combine these segments into a copy of C in G. This will be achieved in Section 3.

Given a digraph G and a partition $\{X_1, X_2\}$ of V(G), we say that (X_1, X_2) is an α -sparse cut if $e_G^+(X_1, X_2) \leq \alpha |X_1| |X_2|$ and X_1, X_2 are non-empty. The following lemma says that if G is a digraph on n vertices with $\delta(G) > (1 + o(1))n$, then there is only one way for G to fail to be a robust outexpander.

Lemma 2.2. Let $0 < \nu, \tau, \alpha, \eta < 1$ such that $\tau < 1/2$ and $\nu \leq \alpha \tau \eta/4$, and let G be a digraph on n vertices with $\delta(G) \geq (1 + \eta)n$. If G has no α -sparse cut, then G is a robust (ν, τ) -outexpander.

Proof. Suppose G has no α -sparse cut, and suppose for a contradiction there exists $S \subseteq V(G)$ with $\tau n \leq |S| \leq (1 - \tau)n$ such that $|RN_{\nu}^{+}(S)| < |S| + \nu n$. Let $A := S \setminus RN_{\nu}^{+}(S)$, $B := S \cap RN_{\nu}^{+}(S), C := RN_{\nu}^{+}(S) \setminus S$, and $D := V(G) \setminus (A \cup B \cup C)$.

First note that we have

$$(\alpha \tau - \nu)n < |C| < |A| + \nu n \tag{2.1}$$

where the upper bound holds by the assumption on S; the lower bound holds because if $|C| \leq (\alpha \tau - \nu)n$, then we would have

$$e_{G}^{+}(S, C \cup D) \leq |S||C| + \nu n(n - |S|) = \left(\frac{|C|}{n - |S|} + \frac{\nu n}{|S|}\right) |S|(n - |S|)$$
$$\leq \left(\frac{\alpha \tau - \nu}{\tau} + \frac{\nu}{\tau}\right) |S|(n - |S|) = \alpha |S|(n - |S|),$$

a contradiction to the fact that there is no α -sparse cut.

We will obtain a contradiction by counting the sum of the degrees of the vertices in A in two different ways. We have

$$|A|(1+\eta)n \le \sum_{v \in A} d_G(v) = \sum_{v \in A} d_G^+(v,A) + \sum_{v \in A} d_G^-(v,A\cup B) + e_G^+(A,B) + e_G(A,C) + e_G(A,D)$$
$$= \sum_{v \in A} d_G^-(v,A) + \sum_{v \in A} d_G^-(v,A\cup B) + e_G^+(A,B) + e_G(A,C) + e_G(A,D)$$

$$< 2\nu n |A| + |A||B| + 2|A||C| + |D|(|A| + \nu n)$$

= |A|(|B| + 2|C| + |D| + 2\nu n) + |D|\nu n

(2.1)
< |A|(|A| + |B| + |C| + |D| + 3\nu n) + |D|\nu n
= |A|(1 + 3\nu)n + |D|\nu n.

Thus, $(\eta - 3\nu)|A| < \nu|D|$ which, since $2\nu \le \alpha \tau/2$ and $3\nu \le \eta/2$ implies that

$$\alpha \tau \eta n/4 \le (\alpha \tau - 2\nu)(\eta - 3\nu)n \stackrel{(2.1)}{<} (\eta - 3\nu)|A| < \nu|D| \le \nu n,$$

a contradiction.

The next technical lemma allows us to "clean-up" a sparse cut to ensure it has some additional properties (which will be needed to prove Proposition 2.1).

Lemma 2.3. Let $k \in \mathbb{N}$, let $0 < \zeta < 1 - \frac{1}{k+1}$, and let $0 < \alpha < \frac{\zeta}{24(k+1)}$. Let G be a digraph on n vertices with $\delta(G) \ge (1 + \frac{1}{k+1} + \zeta)n$ and let $X \subseteq V(G)$ such that

(a) $|X| > (\frac{1}{k+1} + \frac{\zeta}{2})n;$ (b) $\delta(G[X]) \ge (1 + \frac{1}{k+1} + \zeta - \alpha)|X|;$ (c) $d_G(v, X) \ge |X| + (\frac{1}{k+1} + \zeta - \alpha)n$ for all but at most $\alpha^2 n$ vertices $v \in X.$

If G[X] has an α^2 -sparse cut, then G[X] has an α -sparse cut (V_1, V_2) such that for all $i \in [2]$:

(i) $|V_i| > (\frac{1}{k+1} + \frac{\zeta}{2})n;$

(ii)
$$\delta(G[V_i]) \ge (1 + \frac{1}{k+1} + \zeta - 10(k+1)\alpha)|V_i|;$$

(iii) $d_G(v, V_i) \ge |V_i| + (\frac{1}{k+1} + \zeta - 10(k+1)\alpha)n$ for all but at most αn vertices $v \in V_i$.

Note that (i) automatically implies that if X is a set meeting the requirements (a), (b), (c) and $(\frac{1}{k+1} + \frac{\zeta}{2})n < |X| \le (\frac{2}{k+1} + \zeta)n$, then X cannot have an α^2 -sparse cut.

Proof. Suppose that (X_1, X_2) is an α^2 -sparse cut of G[X]. By (a) and (b) we have $|X_i| > 2\alpha n$ for all $i \in [2]$. Indeed, if $|X_i| \leq 2\alpha n$, then (b) implies that every vertex $v \in X_i$ sends double edges to at least $(1/(k+1) + \zeta - \alpha)|X| - 2\alpha n \geq (1/(k+1) + \zeta - \alpha - 2(k+1)\alpha)|X| \geq |X|/(k+1)$ vertices in X_{3-i} ; but then $e_G^+(X_1, X_2) \geq |X_1||X_2|/(k+1) > \alpha^2|X_1||X_2|$, a contradiction as (X_1, X_2) is an α^2 -sparse cut of G[X].

In fact, by combining $|X_i| > 2\alpha n$ with (c) we have

$$|X_i| > \left(\frac{1}{k+1} + \zeta - 2\alpha\right)n$$
 for all $i \in [2]$.

Indeed, if $|X_i| \leq (\frac{1}{k+1} + \zeta - 2\alpha)n$, then by (c), there are $|X_i| - \alpha^2 n > \alpha n$ vertices in X_i that send double edges to at least αn vertices in X_{3-i} , contradicting the fact that (X_1, X_2) is an α^2 -sparse cut.

For all $i \in [2]$, let

$$X'_{i} := \left\{ v \in X_{i} : d_{G}(v, X_{i}) \le |X_{i}| + \left(\frac{1}{k+1} + \zeta - 9(k+1)\alpha\right)n \right\}.$$
7

We now claim that for all $i \in [2]$,

$$|X_i'| \le \frac{\alpha}{6(k+1)}n. \tag{2.2}$$

Indeed, suppose that $|X'_i| > \frac{\alpha}{6(k+1)}n$ for some $i \in [2]$. Then by (c), for all but at most $\alpha^2 n$ vertices $v \in X'_i$, we have

$$d_G(v, X_{3-i}) \ge |X| + \left(\frac{1}{k+1} + \zeta - \alpha\right) n - \left(|X_i| + \left(\frac{1}{k+1} + \zeta - 9(k+1)\alpha\right)n\right) \\ \ge |X_{3-i}| + 8(k+1)\alpha n,$$

which implies that

$$e_G^+(X_1, X_2) \ge (|X_i'| - \alpha^2 n) \cdot 8(k+1)\alpha n > \frac{\alpha}{8(k+1)}n \cdot 8(k+1)\alpha n = \alpha^2 n^2 \ge \alpha^2 |X_1| |X_2|,$$

contradicting the fact that (X_1, X_2) is an α^2 -sparse cut of G[X].

Now set

$$X_2'' := \left\{ v \in X_1' \cup X_2' : d_G(v, X_2 \setminus (X_1' \cup X_2')) \ge \left(1 + \frac{1}{k+1} + \zeta - \alpha \right) |X_2| - \frac{\alpha}{6(k+1)} n \right\},$$

and let $X_1'' := (X_1' \cup X_2') \setminus X_2''$. Note that by (b), (2.2) and the definition of X_1'' , we have that for all $v \in X_1''$,

$$d_G(v, X_1 \setminus (X_1' \cup X_2')) \ge \left(1 + \frac{1}{k+1} + \zeta - \alpha\right) |X_1| - \frac{\alpha}{6(k+1)}n$$

Set $V_1 := (X_1 \setminus X'_1) \cup X''_1$ and $V_2 := (X_2 \setminus X'_2) \cup X''_2$. Note that for all $i \in [2]$, we have

$$|X_i| - \frac{\alpha}{6(k+1)}n \le |V_i| \le |X_i| + \frac{\alpha}{6(k+1)}n.$$
(2.3)

Since $|X_i| > (\frac{1}{k+1} + \zeta - 2\alpha)n$, (2.3) implies that

$$|V_i| > \left(\frac{1}{k+1} + \frac{\zeta}{2}\right)n,\tag{2.4}$$

and thus (i) is satisfied.

If $v \in X_i \setminus X'_i$, then by definition of X'_i , $d_G(v, X_i) \ge \left(1 + \frac{1}{k+1} + \zeta - 9(k+1)\alpha\right) |X_i|$ and so by (2.3) we have that $d_G(v, V_i) \ge \left(1 + \frac{1}{k+1} + \zeta - 9(k+1)\alpha\right) |X_i| - \frac{\alpha}{6(k+1)}n$. Further, if $v \in X''_i$, then $d_G(v, V_i) \ge \left(1 + \frac{1}{k+1} + \zeta - \alpha\right) |X_i| - \frac{\alpha}{6(k+1)}n$. Thus, for all $i \in [2]$,

$$\begin{split} \delta(G[V_i]) &\geq \left(1 + \frac{1}{k+1} + \zeta - 9(k+1)\alpha\right) |X_i| - \frac{\alpha}{6(k+1)}n \\ &\stackrel{(2.3)}{\geq} \left(1 + \frac{1}{k+1} + \zeta - 9(k+1)\alpha\right) \left(|V_i| - \frac{\alpha}{6(k+1)}n\right) - \frac{\alpha}{6(k+1)}n \\ &\geq \left(1 + \frac{1}{k+1} + \zeta - 9(k+1)\alpha\right) |V_i| - \frac{\alpha}{2(k+1)}n \\ &\stackrel{(2.4)}{\geq} \left(1 + \frac{1}{k+1} + \zeta - 10(k+1)\alpha\right) |V_i|, \end{split}$$

so (ii) is satisfied.

By the definition of X'_i and (2.2) we have that for all $i \in [2]$, all but at most $|X'_1| + |X'_2| \leq 1$ $\frac{\alpha}{3(k+1)}n < \alpha n$ vertices $v \in V_i$ have

$$d_{G}(v, V_{i}) \stackrel{(2.3)}{\geq} |X_{i}| + \left(\frac{1}{k+1} + \zeta - 9(k+1)\alpha\right)n - \frac{\alpha}{6(k+1)}n$$

$$\stackrel{(2.3)}{\geq} |V_{i}| + \left(\frac{1}{k+1} + \zeta - 9(k+1)\alpha\right)n - \frac{\alpha}{3(k+1)}n$$

$$> |V_{i}| + \left(\frac{1}{k+1} + \zeta - 10(k+1)\alpha\right)n,$$

and thus (iii) is satisfied.

Finally, we have that (V_1, V_2) is an α -sparse cut since

$$\begin{aligned} e_{G}^{+}(V_{1},V_{2}) &\leq e_{G}^{+}(X_{1},X_{2}) + |X_{1}''||X_{2}''| + |X_{1}||X_{2}''| + |X_{1}''||X_{2}| \\ &\leq \alpha^{2}|X_{1}||X_{2}| + \frac{\alpha^{2}}{36(k+1)^{2}}n^{2} + \frac{\alpha}{3(k+1)}n|X_{1}| + \frac{\alpha}{3(k+1)}n|X_{2}| \\ &\leq 2\alpha^{2}|V_{1}||V_{2}| + \alpha^{2}|V_{1}||V_{2}| + 2\alpha|V_{1}||V_{2}|/5 + 2\alpha|V_{1}||V_{2}|/5 \\ &\leq \alpha|V_{1}||V_{2}|, \end{aligned}$$

where the penultimate inequality uses (2.3) and (2.4) in the form $n < (k+1)|V_i|$ and consequently $|X_i| < (1 + \frac{\alpha}{6})|V_i|$ for all $i \in [2]$.

We are now ready to prove Proposition 2.1.

Proof of Proposition 2.1. Let G be an n-vertex digraph where $n \ge n_0$ and $\delta(G) \ge (1 + \frac{1}{k+1} + \frac{1}{k+1})$ ζ)*n*. The proof proceeds by running an iterative procedure to obtain the desired partition $\{V_1, \ldots, V_t\}$ of V(G). Set $\alpha_b := \alpha^{2^{k-b}}$ for $0 \le b \le k$. Note that $\nu \ll \tau \ll \alpha_b \ll \zeta \ll 1/k$ for any $0 \le b \le k$; this hierarchy will allow us to apply both Lemma 2.2 and Lemma 2.3 throughout the procedure (with α_b playing the role of α).

By Lemma 2.2, either G is a robust (ν, τ) -outexpander or G has an α_0 -sparse cut. In the former case, conditions (i) and (ii) of Proposition 2.1 hold (with t = 1), so we are done.

Thus, suppose G has an α_0 -sparse cut. By Lemma 2.3, there exists an α_1 -sparse cut (V_1^1, V_2^1) of G satisfying conditions (i)–(iii) of the lemma. That is, for $i \in [2]$:

- $|V_i^1| > (\frac{1}{k+1} + \frac{\zeta}{2})n;$
- $\delta(G[V_i^1]) \ge (1 + \frac{1}{k+1} + \zeta 10(k+1)\alpha_1)|V_i^1| \ge (1 + \frac{1}{k+1} + \zeta \alpha_2)|V_i^1|;$
- $d_G(v, V_i^1) \ge |V_i^1| + (\frac{1}{k+1} + \zeta 10(k+1)\alpha_1)n \ge |V_i^1| + (\frac{1}{k+1} + \zeta \alpha_2)n$ for all but at most $\alpha_1 n = \alpha_2^2 n$ vertices $v \in V_i^1$.

If both $G[V_1^1]$ and $G[V_2^1]$ are robust (ν, τ) -out expanders then we set $V_1 := V_1^1$ and $V_2 := V_2^1$ and terminate the procedure. Otherwise, we will continue the iterative procedure as follows.

At each subsequent step of the procedure we will begin with a partition $\{V_1^b, \ldots, V_a^b\}$ of V(G) such that, for each $i \in [a]$:

- (C1) $|V_i^b| > (\frac{1}{k+1} + \frac{\zeta}{2})n;$
- $\begin{array}{l} (C2) \ \delta(G[V_i^b])| \ge (1 + \frac{1}{k+1} + \zeta \alpha_{b+1})|V_i^b|;\\ (C3) \ d_G(v, V_i^b) \ge |V_i^b| + (\frac{1}{k+1} + \zeta \alpha_{b+1})n \text{ for all but at most } \alpha_b n = \alpha_{b+1}^2 n \text{ vertices} \end{array}$ $v \in V_i^b$.

We then proceed as follows: For each class V_i^b such that $G[V_i^b]$ is a robust (ν, τ) -outexpander, we will perform no further partition of V_i^b ; that is, V_i^b will be one of the final classes in the partition $\{V_1, \ldots, V_t\}$ of V(G). So in particular, if all classes V_i^b have this property then we terminate the procedure.

Otherwise, for any other class V_i^b we will have that $G[V_i^b]$ has an α_{b+1}^2 -sparse cut by Lemma 2.2. We can then apply Lemma 2.3 to $X := V_i^b$ to obtain a partition $\{V_{i,1}^b, V_{i,2}^b\}$ of V_i^b such that $(V_{i,1}^b, V_{i,2}^b)$ is an α_{b+1} -sparse cut in $G[V_i^b]$, and so that, for each $j \in [2]$:

- $|V_{i,j}^b| > (\frac{1}{k+1} + \frac{\zeta}{2})n;$
- $\delta(G[V_{i,j}^b]) \ge (1 + \frac{1}{k+1} + \zeta 10(k+1)\alpha_{b+1})|V_{i,j}^b| \ge (1 + \frac{1}{k+1} + \zeta \alpha_{b+2})|V_{i,j}^b|;$ $d_G(v, V_{i,j}^b) \ge |V_{i,j}^b| + (\frac{1}{k+1} + \zeta 10(k+1)\alpha_{b+1})n \ge |V_{i,j}^b| + (\frac{1}{k+1} + \zeta \alpha_{b+2})n$ for all but at most $\alpha_{b+1}n = \alpha_{b+2}^2n$ vertices $v \in V_{i,j}^b$.

Once we have performed this step for all classes V_i^b , by relabeling we obtain a new partition $\{V_1^{b+1}, \ldots, V_{a'}^{b+1}\}$ of V(G) where $a+1 \leq a' \leq 2a$. In particular, we order the classes so that the first class(es) in this new partition are subsets of V_1^b , the next class(es) are subsets of V_2^b , and so on. Moreover, if a class V_i^b was partitioned in the last step, then the class $V_{i,1}^b$ must appear immediately before the class $V_{i,2}^b$ in the new partition $\{V_1^{b+1},\ldots,V_{a'}^{b+1}\}$. Note that $\{V_1^{b+1},\ldots,V_{a'}^{b+1}\}$ satisfies (C1)–(C3) (with b+1 and a' playing the roles of b and a, respectively). We then continue to the next step of the procedure.

Crucially, this procedure must terminate for some $b \leq k-1$. Indeed, at every step of the process we either terminate the procedure (if all classes induce robust (ν, τ) -outexpanders), or create a new partition of V(G) with at least one more partition class than before. By (C1), we can have at most k classes in $\{V_1^b, \ldots, V_a^b\}$; this therefore means the procedure does terminate after at most k-1 steps. Let $\{V_1,\ldots,V_t\}$ denote the partition at the end of this procedure. Then (C1) implies that Proposition 2.1(i) holds.

Since the procedure only terminates when each class V_i in the partition induces a robust (ν, τ) -outexpander, together with (C2) this implies that Proposition 2.1(ii) holds.

If $t \geq 2$, consider any V_i and V_j where $1 \leq i < j \leq t$. By the way in which we construct and order our partitions at every step, it must be the case that there is some $b \in [k-1]$ and $V_{i'}^b, V_{j'}^b \subseteq V(G)$ such that $V_i \subseteq V_{i'}^b; V_j \subseteq V_{j'}^b; (V_{i'}^b, V_{j'}^b)$ is an α_b -sparse cut in $G[V_{i'}^b \cup V_{j'}^b]$. As $|V_i|, |V_i| \ge n/(k+1)$ this implies that

$$e_{G}^{+}(V_{i}, V_{j}) \leq \alpha_{b} \cdot |V_{i'}^{b}| |V_{j'}^{b}| \leq \alpha_{k-1}(k+1)^{2} |V_{i}| |V_{j}| \leq \alpha |V_{i}| |V_{j}|,$$

which implies that Proposition 2.1(iv) holds.

Finally, if $t \ge 2$, suppose for a contradiction that $e_G^-(V_i, V_j) \le \frac{n^2}{(k+1)^2}$ for some $1 \le i < i$ $j \leq t$. If $|V_i| \leq |V_i|$, using Proposition 2.1(iv) we obtain that

$$|V_i|\left(1+\frac{1}{k+1}+\zeta\right)n-2|V_i|^2 \le e_G(V_i,V(G)\setminus V_i) \le |V_i|(n-|V_i|-|V_j|)+\frac{n^2}{(k+1)^2}+\alpha n^2,$$

which implies that

$$\left(1 + \frac{1}{k+1} + \zeta\right)n \le n - |V_j| + |V_i| + \frac{n^2}{(k+1)^2|V_i|} + \frac{\alpha n^2}{|V_i|} < \left(1 + \frac{1}{k+1} + \zeta\right)n,$$

a contradiction. Similarly, if $|V_j| \leq |V_i|$, we analogously obtain a contradiction by considering $e_G(V_j, V(G) \setminus V_j)$. Thus, Proposition 2.1(iii) holds.

3. Embedding the Hamilton cycle

Our main result in this section is the following.

Proposition 3.1. Let $0 < 1/n_0 \ll \rho \ll \nu \ll \tau \ll \eta \ll 1$ and let $n \ge n_0$. If G is an n-vertex digraph and $\{V_1, \ldots, V_t\}$ is a partition of V(G) such that:

- (i) for all $i \in [t]$, $|V_i| \ge \eta n$ and consequently $t \le \frac{1}{n}$;
- (ii) for all $i \in [t]$, $G[V_i]$ is a robust (ν, τ) -outexpander with $\delta^0(G[V_i]) \ge \eta |V_i|$;
- (iii) if $t \ge 2$, then for all $1 \le i < j \le t$, $e_G^+(V_i, V_j) \ge \frac{n}{a^2}$,

then G contains every orientation of a Hamilton cycle, except possibly the directed Hamilton cycle.

Note that Theorem 1.3 follows easily from Propositions 2.1 and 3.1.

Proof of Theorem 1.3. Let $\eta > 0$ and define $k \in \mathbb{N}$ such that $1/(k+1) \ll \eta$. Set $\eta' := 1/(k+1)$ and define additional constants so that

$$0 < 1/n_0 \ll \rho \ll \nu \ll \tau \ll \alpha \ll \zeta \ll \eta'.$$

Let G be a digraph on $n \ge n_0$ vertices with $\delta(G) \ge (1 + \eta)n \ge (1 + \eta' + \zeta)n$. By applying Proposition 2.1, and reversing the ordering of the partition of V(G) outputted, we obtain a partition $\{V_1, \ldots, V_t\}$ of V(G) so that:

- for all $i \in [t]$, $|V_i| \ge (\eta' + \frac{\zeta}{2})n$;
- for all $i \in [t]$, $G[V_i]$ is a robust (ν, τ) -outexpander with $\delta(G[V_i]) \ge (1 + \eta' + \frac{\zeta}{2})|V_i|$, and thus $\delta^0(G[V_i]) \ge \eta'|V_i|$;
- if $t \ge 2$, then for all $1 \le i < j \le t$, $e_G^+(V_i, V_j) > \frac{n^2}{(k+1)^2}$.

Applying Proposition 3.1 (with η' playing the role of η) implies that G contains every orientation of a Hamilton cycle, except for perhaps the directed Hamilton cycle (in the case when G is not strongly connected).

Before proceeding with the proof of Proposition 3.1 we need some further notation. A segment of an oriented cycle C (resp. oriented path P) is an oriented path that forms an induced subgraph of C (resp. P). A directed segment of an oriented cycle or path is a segment that induces a directed path. Note that we will often write a segment in the form $x_1 \ldots x_{\ell}$ to indicate the ordered sequence of vertices this segment contains; this notation does not tell us anything about how the edges in the segment are oriented. Given a segment P of an oriented cycle or path C, a non-endpoint vertex v of P is a switch if it is either a source or a sink in P.

The proof of Proposition 3.1 splits into two cases depending on whether the orientation of a Hamilton cycle we wish to embed contains a directed segment of order at least βn or not. The following observation explicitly describes the two cases.

Observation 3.2. Let $0 < \beta \leq 1$ and let C be an oriented cycle on $n \geq 3$ vertices. Either

(i) C contains a directed segment on $|\beta n|$ vertices, or

(ii) every segment of C on $|\beta n|$ vertices contains a switch.

The next observation will allow us to connect up oriented paths that lie in different vertex classes in the partition of V(G) in Proposition 3.1.

Observation 3.3. Let $\rho > 0$, let G be an n-vertex digraph and let $X, Y \subseteq V(G)$ be disjoint with $e_G^+(X,Y) \ge \frac{n}{\rho}$. If $X' := \{x \in X : d_G^+(x,Y) \ge \frac{1}{\rho}\}$ and $Y' := \{y \in Y : d_G^-(y,X) \ge \frac{1}{\rho}\}$, then $|X'|, |Y'| \ge \frac{1}{\rho}$.

Proof. If say $|X'| < \frac{1}{\rho}$, then we have $e_G^+(X,Y) < |X'||Y| + (|X| - |X'|)\frac{1}{\rho} < \frac{1}{\rho}|Y| + \frac{1}{\rho}|X| \le \frac{n}{\rho}$, a contradiction.

We also need a result that allows us to span each robust outexpander $G[V_i]$ with a collection of oriented paths (which will then be connected together to form our desired orientation of a Hamilton cycle in G). This will be derived from a strengthening of the following theorem of Taylor [20, Theorem 49].

Theorem 3.4 (Taylor [20]). Let $0 < 1/n_0 \ll \nu \ll \tau \ll \eta < 1$ and let G be a digraph on $n \ge n_0$ vertices. If G is a robust (ν, τ) -outexpander with $\delta^0(G) \ge \eta n$, then G contains every orientation of a Hamilton cycle.

One can modify the proof of Theorem 3.4 to obtain the following.

Theorem 3.5 (Universally k-linked). Let $0 < 1/n_0 \ll \beta \ll \nu \ll \tau \ll \eta$, let $k \in \mathbb{N}$ with $k \leq 1/\beta^2$, let G be a digraph on $n \geq n_0$ vertices, and let Q_1, \ldots, Q_k be a collection of oriented paths with $|Q_i| =: \ell_i \geq 1/\beta$ for all $i \in [k]$ such that $\ell_1 + \cdots + \ell_k = n$. If G is a robust (ν, τ) -outexpander with $\delta^0(G) \geq \eta n$, then for all distinct vertices $u_1, \ldots, u_k, v_1, \ldots, v_k \in V(G)$, there exists a collection of disjoint oriented paths P_1, \ldots, P_k in G such that for all $i \in [k]$, P_i starts with u_i and ends with v_i , and P_i is a copy of Q_i .

An explanation of how to deduce Theorem 3.5 from Taylor's work [20] is given in the appendix.

Finally, we need the following simple observation which is just an easy special case of Havet and Thomassé's theorem [13].

Observation 3.6. Let T be a transitive tournament. For all oriented paths Q with $|Q| \leq |T|$, there is a copy of Q in T.

We now proceed to the proof of Proposition 3.1.

Proof of Proposition 3.1. We first choose a constant β so that $\rho \ll \beta \ll \nu$. Let G be an *n*-vertex digraph as in the proposition. Note we may assume that $t \geq 2$, otherwise the proposition follows immediately from Theorem 3.4.

Let C be an n-vertex oriented cycle that is not a directed cycle. We will define an embedding $f: V(C) \to V(G)$ of C into G. We will split into cases depending on how C is oriented. In each case, we will first select the edges used in f that go between different vertex classes V_i, V_j for each $1 \le i < j \le t$ (and possibly a small number of other edges); we then apply Theorem 3.5 to find collections of oriented paths in each $G[V_i]$ that, together with the previously selected edges, complete the embedding f.

Case 1: There exists a directed segment of C on $\lfloor \beta n \rfloor$ vertices. Let $\ell \geq \lfloor \beta n \rfloor$ denote the number of vertices in the longest directed segment of C. For each $j \in [t]$, let $\ell_j := \sum_{i=1}^j |V_i|$ and set $\ell_0 := 0$. Note that $\ell_t = n$.

Subcase 1(a): $0 \le n - \ell \le \eta n/2$. Write $C = x_1 \dots x_n x_1$ where x_1 is a source in C, x_ℓ is a sink in C and $P := x_1 \dots x_\ell$ is a longest directed segment of C. In particular, $x_1x_2, x_1x_n \in E(C)$. Let $P' := x_{\ell+1} \dots x_n$ be the segment of C from $x_{\ell+1}$ to x_n ; note that P' is empty if $\ell = n$.

For each $j \in [t]$, define $P_j := x_{\ell_{j-1}+1} \dots x_{\ell_j}$ to be the segment of C that starts at $x_{\ell_{j-1}+1}$ and ends at x_{ℓ_j} . Note that for $j \in [t-1]$, P_j is contained in P and so is a directed segment of C, whereas P_t contains P' (so may not be a *directed* segment). Note that the edges in $E(C) \setminus E(P_1 \cup \dots \cup P_t)$ are precisely $x_1 x_n$ and $x_{\ell_j} x_{\ell_j+1} \in E(C)$ for each $j \in [t-1]$.

We will define f so that P_j is embedded into $G[V_j]$ for each $j \in [t]$. First, we choose $f(x_1) \in V_1$; $f(x_n) \in V_t$; $f(x_{\ell_j}) \in V_j$ and $f(x_{\ell_j+1}) \in V_{j+1}$ for each $j \in [t-1]$ so that:

- all selected vertices in this step are distinct;
- $f(x_1)f(x_n) \in E(G);$
- $f(x_{\ell_i})f(x_{\ell_i+1}) \in E(G)$ for each $j \in [t-1]$.

Note that we can select such vertices in G by Observation 3.3.

Next, for each $j \in [t]$, we find a copy P'_j of P_j in $G[V_j]$ that starts at $f(x_{\ell_{j-1}+1})$ and ends at $f(x_{\ell_j})$. Indeed, we obtain these oriented paths by applying Theorem 3.5 to each of $G[V_1], \ldots, G[V_t]$.

By concatenating the paths P'_1, \ldots, P'_t and the edges we selected between vertex classes, we obtain our desired embedding f of C in G.

Subcase 1(b): $\eta n/2 < n - \ell \le n - \lfloor \beta n \rfloor$. Write $C = x_1 \dots x_n x_1$ where x_1 is a source in $C, x_{n-\ell+2}$ is a sink in C and $P := x_1 x_n \dots x_{n-\ell+2}$ is a longest directed segment of C. Let $P' := x_2 \dots x_{n-\ell+1}$ be the segment of C from x_2 to $x_{n-\ell+1}$. Note that $|P'| = n - \ell > \eta n/2$. Set $D := \lfloor \rho n \rfloor$ and $q := \lceil \frac{n-\ell}{D} \rceil < 1/\rho$ and partition P' into segments $P'_1 := x_2 \dots x_{n_1}$; $P'_2 := x_{n_1+1} \dots x_{n_2}; \dots; P'_q := x_{n_{q-1}+1} \dots x_{n-\ell+1}$ that are chosen to be as equal sized as possible. In particular, for all $i \in [q]$, certainly $D/2 \le |P'_i| \le D$.

Each segment P'_i will be embedded fully into one of our vertex classes V_j . On the other hand, P will be embedded across all of the vertex classes V_1, \ldots, V_t (see Figure 1). Before we can embed these segments, we need to construct the edges of C that will go between the vertex classes.

To help with this, we define the auxiliary oriented path $Q := w_1 w_2 \dots w_q$ such that for all $i \in [q-1]$, $w_i w_{i+1} \in E(Q)$ if $x_{n_i} x_{n_i+1} \in E(P')$, and $w_{i+1} w_i \in E(Q)$ if $x_{n_i+1} x_{n_i} \in E(P')$.

For all $j \in [t]$, let $U_j := \left\{ u_1^j, \dots, u_{\lfloor \frac{|V_j| - \rho_n}{D} \rfloor}^j \right\}$. Consider an auxiliary transitive tournament T on vertex set $U_1 \cup \dots \cup U_t$ such that $u_k^j u_{k'}^{j'} \in E(T)$ if and only if j < j' or j = j' and k < k'. Note that

$$|T| = \sum_{j \in [t]} \left\lfloor \frac{|V_j| - \rho n}{D} \right\rfloor \ge \left\lceil \frac{(1 - \beta/2)n}{D} \right\rceil \ge \left\lceil \frac{n - \ell}{D} \right\rceil = |Q|.$$

By Observation 3.6, there is an embedding ϕ of Q into T.

We now use this auxiliary embedding ϕ as a 'blueprint' to determine in which of the classes V_1, \ldots, V_t each segment P'_i will be embedded into: If $\phi(w_i) \in U_j$, then we will eventually embed P'_i into V_j . Furthermore if $\phi(w_i) \in U_j$ and $\phi(w_{i+1}) \in U_{j'}$ and $w_i w_{i+1} \in E(Q)$, then by the way we defined T it must be the case that $j \leq j'$. If j < j', this ensures that we can use Observation 3.3 to find an edge in G from V_j to $V_{j'}$ that will connect $f(x_{n_i})$ (the last vertex of P'_i) to $f(x_{n_i+1})$ (the first vertex of P'_{i+1}); if j = j' we use that $\delta^0(G[V_j]) \geq \eta |V_j|$ to find an edge in $G[V_j]$ that will connect $f(x_{n_i})$ to $f(x_{n_i+1})$. One can argue similarly if $w_{i+1}w_i \in E(Q)$ (with the roles of j and j' switched).

FIGURE 1. Case 1(b): An example with q = 4

We now know in which classes we wish to embed each segment P'_i of P'. This tells us how many vertices are 'left' in each class V_j that we need to cover using P. In particular, note that by the way we defined T, there are at least ρn vertices in each class V_j that will not be used for embedding P'_i ;² so these vertices will have to be covered by P. We will embed P so that it goes through each class V_1, \ldots, V_t sequentially. That is, x_1 will be embedded in V_1 and we continue to use vertices in V_1 until the correct number of vertices are covered, then we jump over to V_2 (using a single edge between V_1 and V_2) and repeat this process; finally $x_{n-\ell+2}$ will be embedded into V_t . Before we can embed the whole of P, for each $j \in [t-1]$, we need to choose the single edge in G that goes between V_j and V_{j+1} that will be used in the embedding of P. We can use Observation 3.3 to select such edges so that they are all disjoint, and disjoint from all the edges selected previously that will be used to connect up the segments P'_i .

Also note that if $\phi(w_1) \in U_{j_1}$, then regardless of the value of j_1 , we can use Observation 3.3 (or the fact that $\delta^0(G[V_1]) \ge \eta |V_1|$ if $j_1 = 1$) to find an edge from V_1 to V_{j_1} that will connect $f(x_1)$ to $f(x_2)$. Likewise, if $\phi(w_q) \in U_{j_q}$, then regardless of the value of j_q we can find an edge from V_{j_q} to V_t which will connect $f(x_{n-\ell+1})$ to $f(x_{n-\ell+2})$.

In summary, we now have selected all the edges in G required to connect between the segments P'_1, \ldots, P'_q, P , and all edges that will go between different classes in the embedding of P into G. One can now apply Theorem 3.5 to each induced subgraph $G[V_i]$ to obtain the embeddings of the segments P'_1, \ldots, P'_q as well as the remaining edges needed for P. This therefore completes the embedding f of C into G.

²Specifically, at most $\lfloor \frac{|V_j| - \rho n}{D} \rfloor$ of the segments P'_i (each of which contain at most D vertices) will be embedded into a class V_i .

Case 2: Every segment on $\lfloor \beta n \rfloor$ **vertices contains a switch.** Write $C = x_1 x_2 \dots x_n x_1$ where x_1 is a source in C. In this case we have the following crucial property:

Every segment of C on at least $2\beta n$ vertices contains both a source and a sink. (3.1)

Our plan is to partition C into t segments P_1, \ldots, P_t and construct an embedding f: $V(C) \to V(G)$ of C in G so that for all $i \in [t-1]$, $f(P_i) \subseteq V_i \cup V_{i+1}$ and $f(P_t) \subseteq V_t$, and such that for all $i \in [t]$, $f(P_i)$ starts and ends in V_i . We now explain the steps we take to achieve this embedding.

Step 1: Partitioning C into t segments. Set $n_0 := 0$ and $n_t := n$. Let $P_1 := x_{n_0+1} \dots x_{n_1}$ be the minimal segment in C that starts at $x_{n_0+1} = x_1$ and where $x_{n_1}x_{n_1+1} \in E(C)$ and $|P_1| \ge |V_1|$; note that as we are in Case 2, P_1 exists and $|P_1| \le |V_1| + \beta n$. Since $|V_2| \ge \eta n \gg \beta n$, we have that $|P_1|$ is much smaller than $|V_1| + |V_2|$.

Let $s \in [t-2]$ and suppose we have chosen segments $P_1 = x_{n_0+1} \dots x_{n_1}$, $P_2 = x_{n_1+1} \dots x_{n_2}$, $\dots, P_s = x_{n_{s-1}+1} \dots x_{n_s}$ such that for all $i \in [s]$, P_i is the minimal segment of C that starts at $x_{n_{i-1}+1}$ such that $x_{n_i}x_{n_i+1} \in E(C)$ and $|V_1| + \dots + |V_i| \leq |P_1| + \dots + |P_i| \leq |V_1| + \dots + |V_i| + \beta n$. We then choose $P_{s+1} := x_{n_s+1} \dots x_{n_{s+1}}$ minimally such that $x_{n_{s+1}}x_{n_{s+1}+1} \in E(C)$ and $|P_1| + \dots + |P_{s+1}| \geq |V_1| + \dots + |V_{s+1}|$; again this is possible as we are in Case 2, and in fact we have $|P_1| + \dots + |P_{s+1}| \leq |V_1| + \dots + |V_{s+1}| + \beta n$. Finally, we let $P_t := x_{n_{t-1}+1} \dots x_{n_t}$ and note that by the way the other segments P_i were chosen, we have $|V_t| - \beta n \leq |P_t| \leq |V_t|$.

Step 2: Setting up the connections and fixing the imbalance. Ideally we would like to have had that $|P_i| = |V_i|$ for all $i \in [t]$. Then we could embed P_1 fully into V_1 and then jump over to V_2 and embed P_2 there, and so forth, to obtain an embedding of C into G. However, we have that $|P_i| \leq |V_i| + \beta n$, and in particular there may be a gap between $\sum_{i=1}^{s} |P_i|$ and $\sum_{i=1}^{s} |V_i|$ for some of the $s \in [t-1]$.

As such, in this step we will embed constantly-many segments of C into G in such a way that along C there is at least a large constant gap between consecutive pairs of such segments. The goal is to make all of the required connections between V_i and V_{i+1} for each $i \in [t-1]$, while at the same time correcting the gap between $\sum_{i=1}^{s} |P_i|$ and $\sum_{i=1}^{s} |V_i|$ for each $s \in [t-1]$.

We begin by using Observation 3.3 to obtain a matching M in G consisting of one edge $v_1v_n = v_{n_0+1}v_{n_t}$ from V_1 to V_t , and for all $i \in [t-1]$, one edge $v_{n_i}v_{n_i+1}$ from V_i to V_{i+1} . For each $i \in [t]$, set $f(x_{n_i}) := v_{n_i}$, and for each $i \in [t-1] \cup \{0\}$, set $f(x_{n_i+1}) := v_{n_i+1}$.

For each $s \in [t-1]$, set $d_s := \sum_{j=1}^{s} |P_j| - \sum_{j=1}^{s} |V_j| \ge 0$. If $d_s = 0$ for all $s \in [t-1]$, we move on to the next step; so suppose $d_s > 0$ for some $s \in [t-1]$, and consider any such s. The minimality of P_s combined with the fact that we are in Case 2 implies that x_{n_s} is source in C and $d_s \le \beta n$. Let $a_s + 1 < n_s$ be a maximal index such that x_{a_s+1} is a sink in C. Note that $P_s^* := x_{n_s} x_{n_s-1} \dots x_{n_s-d_s} \dots x_{a_s+1}$ is a directed segment on at most βn vertices (and on at least $d_s + 1$ vertices).

We now have two subcases that we first describe informally: Either $0 < d_s \leq \frac{\eta}{6\beta}$ and we are able to fix the imbalance by embedding d_s sinks from P_s in V_{s+1} (in a way that will be made precise shortly), or $\frac{\eta}{6\beta} < d_s \leq \beta n$ and we use $\lfloor \frac{\eta}{12\beta} \rfloor$ sinks as before, together with the segment $P_s^* = x_{n_s} x_{n_s-1} \dots x_{a_s+1}$ to fix the imbalance (roughly by embedding $x_{a_s+d_s-\lfloor\frac{\eta}{12\beta}\rfloor}\ldots x_{a_s+1}$ in V_{s+1} , x_{a_s} in V_s , and $x_{n_s}\ldots x_{a_s+d_s-\lfloor\frac{\eta}{12\beta}\rfloor+1}$ in V_s). We now make these subcases precise.

FIGURE 2. Case 2, Step 2

First suppose that $0 < d_s \leq \frac{\eta}{6\beta}$. Since $|V_s| \geq \eta n$, how we defined n_s and n_{s-1} , together with (3.1), implies that $n_s - n_{s-1} \geq \eta n - 2\beta n$. Using this with (3.1) ensures that we can select d_s sinks $x_{k_1^s}, \ldots, x_{k_{d_s}^s}$ on P_s where

- (D1) $n_{s-1} + 2\beta n < k_1^s < k_2^s < \dots < k_{d_s}^s < n_s 2\beta n;$
- (D2) $x_{k_1^s}, \ldots, x_{k_{d_s}^s}$ do not lie on the directed segment P_s^* ;
- (D3) for all $1 \le i < j \le d_s$ we have that $k_j^s k_i^s \ge \beta n$.

In fact, notice (D2) follows immediately from (D1) and the definition of P_s^* .

We now use Observation 3.3 to find d_s disjoint subgraphs $\Lambda_1^s, \ldots, \Lambda_{d_s}^s$ of G where, for each $i \in [d_s]$, $V(\Lambda_i^s) =: \{v_{k_i^s-1}, v_{k_i^s+1}, v_{k_i^s}\}$ with $v_{k_i^s-1}, v_{k_i^s+1} \in V_s$ and $v_{k_i^s} \in V_{s+1}$ such that $E(\Lambda_i^s) = \{v_{k_i^s-1}v_{k_i^s}, v_{k_i^s+1}v_{k_i^s}\}$ (see Figure 2a). Further, each Λ_i^s is disjoint from the matching M we previously selected in G and disjoint from any other Λ_i^t 's we may have chosen previously (for t < s). Now for all $i \in [d_s]$, set $f(x_{k_i^s}) := v_{k_i^s}, f(x_{k_i^s-1}) := v_{k_i^s-1}$, and $f(x_{k_i^s+1}) := v_{k_i^s+1}$. This ensures that we will embed precisely d_s vertices of P_s into V_{s+1} .

Next suppose that $\frac{\eta}{6\beta} < d_s \leq \beta n$. Set $d'_s := \lfloor \frac{\eta}{12\beta} \rfloor$. Analogously to before, select d'_s sinks $x_{k_1^s}, \ldots, x_{k_{d'_s}^s}$ on P_s satisfying (D1)–(D3). We then use Observation 3.3 to find d'_s disjoint subgraphs $\Lambda_1^s, \ldots, \Lambda_{d'_s}^s$ of G where, for each $i \in [d'_s]$, $V(\Lambda_i^s) =: \{v_{k_i^s-1}, v_{k_i^s+1}, v_{k_i^s}\}$ with $v_{k_i^s-1}, v_{k_i^s+1} \in V_s$ and $v_{k_i^s} \in V_{s+1}$ such that $E(\Lambda_i^s) = \{v_{k_i^s-1}v_{k_i^s}, v_{k_i^s+1}v_{k_i^s}\}$. Further, each Λ_i^s is disjoint from the matching M we previously selected in G and disjoint from any other Λ_i^t 's we may have chosen previously (for t < s). Now for all $i \in [d'_s]$, set $f(x_{k_i^s}) := v_{k_i^s}$, $f(x_{k_i^s-1}) := v_{k_i^s-1}$, and $f(x_{k_i^s+1}) := v_{k_i^s+1}$.

Next we use Observation 3.3 to find disjoint edges $v_{a_s}v_{a_s+1}$ and $v_{a_s+d_s-d'_s+1}v_{a_s+d_s-d'_s}$ from V_s to V_{s+1} in G (that are disjoint from M and all the Λ_i^s). Set $f(x_{a_s}) := v_{a_s}$, $f(x_{a_s+1}) := v_{a_s+d_s-d'_s+1}$, $f(x_{a_s+d_s-d'_s+1}) := v_{a_s+d_s-d'_s+1}$, and $f(x_{a_s+d_s-d'_s}) := v_{a_s+d_s-d'_s}$ (see Figure 2b).

Thus, when we finish the embedding f of C into G in Step 3, precisely d_s vertices from P_s will be embedded into V_{s+1} : d'_s vertices playing the roles of the sinks $x_{k_1^s}, \ldots, x_{k_{d'_s}^s}$ and the $d_s - d'_s$ vertices that are in the segment $x_{a_s+d_s-d'_s} \ldots x_{a_s+1}$ of C (which lies fully in

 P_s^*). Note too that, since $|P_s^*| \ge d_s$, this segment $x_{a_s+d_s-d'_s} \dots x_{a_s+1}$ is of distance at least $d'_s = \lfloor \frac{\eta}{12\beta} \rfloor$ from x_{n_s} in C. This property is vital in ensuring we can apply Theorem 3.5 in Step 3.

Step 3: Finishing the embedding. At this point we have embedded only a constant number of segments of C with the key property that between any two already embedded segments of C, there is at least a large constant gap (at least $d'_s = \lfloor \frac{\eta}{12\beta} \rfloor$) between the ends of the segments. In particular, this is ensured by (D1), (D3), and (in the case when $\frac{\eta}{6\beta} < d_s \leq \beta n$) by the choice of the segment $x_{a_s+d_s-d'_s} \dots x_{a_s+1}$ of P_s^* that we have chosen to be embedded into V_{s+1} . For each $i \in [t]$, let V'_i be the subset of V_i obtained by deleting all middle (sink) vertices in the subgraphs Λ^s_j of G obtained in Step 2. Note that $|V_i \setminus V'_i| \leq \frac{\eta}{6\beta}$; thus, each $G[V'_i]$ is a robust $(\nu/2, 2\tau)$ -outexpander with $\delta^0(G[V'_i]) \geq \eta n/2$. Therefore, to finish the embedding f, we apply Theorem 3.5 to each $G[V'_i]$ to embed the remaining segments of C into the appropriate places.

4. Concluding remarks

In this paper we have asymptotically determined the minimum degree threshold for forcing an arbitrary orientation of a Hamilton cycle in a digraph (Theorem 1.3). It would be interesting to obtain an exact version of this result.

Problem 4.1. If G is a sufficiently large n-vertex digraph with $\delta(G) \ge n+1$, then does G contain every orientation of a Hamilton cycle (except for the directed Hamilton cycle when G is not strongly connected)?

Recall that one cannot lower the minimum degree condition in Problem 4.1 for antidirected Hamilton cycles [4]. However, it would be interesting to know if a minimum degree of $\delta(G) \geq n$ is already enough to force every orientation of a Hamilton cycle, other than the directed and anti-directed ones.

As mentioned in the introduction, a positive answer to the following problem would provide a common generalization of Havet and Thomassé's tournament theorem [13] and Corollary 1.2.

Problem 4.2. If G is a sufficiently large n-vertex digraph with $\delta(G) \ge n-1$, then does G contain every orientation of a Hamilton path?

From the perspective of obtaining results that unify the minimum degree setting and the setting of tournaments, it may also be interesting to find a characterization of all those (strongly connected) *n*-vertex digraphs with $\delta(G) \ge n-1$ that do not contain every orientation of a Hamilton cycle.

Finally, we note that Proposition 2.1 provided crucial structure that we exploited in the proof of Theorem 1.3. This tool is likely to have several further applications; we will explore this in future work.

5. Appendix: Proofs of Theorems 1.6 and 3.5

5.1. **Deriving Theorem 3.5.** In this subsection we prove Theorem 3.5. Before this, we introduce the main results used to obtain Theorem 3.5.

The following lemma of Taylor [20] allows us to find any not too short, not too long oriented path between any pair of vertices in a robust outexpander.³

Lemma 5.1 (Taylor [20]). Let $0 < 1/n_0 \ll \nu \leq \tau \ll \eta \ll 1$, let $n \geq n_0$, and let $\lceil 2/\nu^3 \rceil \leq k \leq \nu^3 n/4$. If G is an n-vertex digraph with $\delta^0(G) \geq \eta n$ such that G is a robust (ν, τ) -outexpander, then for all distinct $x, y \in V(G)$ and all oriented paths P of length k, there is a copy of P in G that starts at x and ends at y.

Lemma 5.1 will allow us to find all the required short oriented paths in the proof of Theorem 3.5. The next two results will enable us to construct the longer oriented paths. The first of these results generalizes [20, Lemma 60].

Lemma 5.2 (Splitting robust expanders). Let $0 < 1/n_0 \ll \nu' \ll \varepsilon \ll \nu \ll \tau \ll \tau' \ll \eta$ and let $n \ge n_0$ be an integer. Let $m_0, m_1, \ldots, m_t \in \mathbb{N} \cup \{0\}$ such that for all $i \in [t], m_i \ge \varepsilon^{1/3}n$; $m_0 \le \varepsilon^{1/4}n; m_0 + m_1 + \cdots + m_t = n$. Suppose that G is an n-vertex digraph with $\delta^0(G) \ge \eta n$ and G is a robust (ν, τ) -outexpander. If $W_0 \subseteq V(G)$ is any set of m_0 vertices, then there is a partition $\{W_0, W_1, \ldots, W_t\}$ of V(G) such that for all $i \in [t]$:

- $|W_i| = m_i$ and $G[W_i]$ is a robust (ν', τ') -outexpander;
- $d_G^+(x, W_i), d_G^-(x, W_i) \ge \eta m_i/4$ for every $x \in V(G)$.

Lemma 60 in [20] yields the $W_0 = \emptyset$, t = 2 case of the lemma. In fact, the argument there can easily be tweaked to prove Lemma 5.2. As such, we only provide a detailed proof sketch.

Sketch proof of Lemma 5.2. Define an additional constant d so that

$$0 < 1/n_0 \ll \nu' \ll \varepsilon \ll d \ll \nu \ll \tau \ll \tau' \ll \eta.$$

Let G be a digraph on $n \ge n_0$ vertices as in the statement of the lemma. Let $G' := G \setminus W_0$ and set n' := |G'|. As $|W_0| \le \varepsilon^{1/4}n$, G' is a robust $(\nu/2, 2\tau)$ -outexpander with $\delta^0(G') \ge \eta n'/2$.

Apply the regularity lemma for digraphs to G' with parameters ε, d (see, e.g., [20, Lemma 39] for the version of the regularity lemma that we use). We therefore obtain a partition of V(G') into clusters V_1, \ldots, V_k of the same size m and an exceptional set V_0 , with $|V_0| \leq \varepsilon n'$. Crucially, for every distinct $i, j \in [k]$, (V_i, V_j) forms an ε -regular pair in G' of density either 0 or at least d.

We now randomly partition V(G') into classes W_1, \ldots, W_t where $|W_i| = m_i$ for all $i \in [t]$. By Chernoff's bound for the hypergeometric distribution, with high probability, for each $i \in [t]$ and $x \in V(G)$ we have $d_G^+(x, W_i), d_G^-(x, W_i) \ge \eta m_i/4$. Moreover, with high probability, for each $i \in [t]$ and $j \in [k]$, we have

$$|W_i \cap V_j| \ge (1-\varepsilon)m \cdot \frac{m_i}{n} \ge \varepsilon^{1/2}m.$$

For each $i \in [t]$ and $j \in [k] \cup \{0\}$, set $V_j^i := W_i \cap V_j$. Thus, $V_0^i, V_1^i, \ldots, V_k^i$ is a partition of W_i . Moreover, as $|V_j^i| \ge \varepsilon^{1/2} m$ for each $j \in [k]$, we have the following property:

(P1) If (V_{j_1}, V_{j_2}) forms an ε -regular pair of density at least d in G', then $(V_{j_1}^i, V_{j_2}^i)$ forms an $\varepsilon^{1/2}$ -regular pair of density at least $d - \varepsilon$ in $G'[W_i]$.

³Formally one applies Proposition 48 and Lemma 58 from [20] to obtain Lemma 5.1.

In particular, (P1) implies that the reduced digraph R_i of $G'[W_i]$ is the same as the reduced digraph R of G'. As G' is a robust $(\nu/2, 2\tau)$ -outexpander with $\delta^0(G') \ge \eta n'/2$, [20, Lemma 50] implies that R is a robust $(\nu/4, 4\tau)$ -outexpander with $\delta^0(R) \ge \eta k/4$.

Finally, as argued at the end of the proof of Lemma 60 in [20], since the reduced digraph $R_i = R$ of $G'[W_i]$ is a robust $(\nu/4, 4\tau)$ -outexpander, this implies that $G'[W_i] = G[W_i]$ is a robust (ν', τ') -outexpander. Indeed, if one considers any set $S \subseteq W_i$ where $\tau'm_i \leq |S| \leq (1 - \tau')m_i$, S must intersect many V_1^i, \ldots, V_k^i significantly (certainly more than τk of these classes). Let Q be the set of such significantly intersected V_j^i . In particular, we have that the robust outneighborhood $RN_{\nu/4}^+(Q)$ of Q in R_i satisfies $|RN_{\nu/4}^+(Q)| \geq |Q| + \nu k/4$. Moreover, most vertices in each class $V_j^i \in RN_{\nu/4}^+(Q)$ lie in the ν' -robust out-neighborhood $RN_{\nu'}^+(S)$ of S in $G[W_i]$. A simple calculation now implies that $|RN_{\nu'}^+(S)| \geq |S| + \nu'm_i$, as desired. \Box

We also require the following generalization of Theorem 3.4.

Theorem 5.3 (Universally Hamilton connected). Let $0 < 1/n_0 \ll \nu \ll \tau \ll \eta$ and let G be a digraph on $n \ge n_0$ vertices. If $\delta^0(G) \ge \eta n$ and G is a robust (ν, τ) -outexpander, then for all distinct $x, y \in V(G)$ and any oriented path P on n vertices, there exists a copy of P in G that starts at x and ends at y.

This result is easily derived from the following version of Theorem 3.4.

Theorem 5.4. Let $0 < 1/n_0 \ll \nu \ll \tau \ll \eta$ and let G be a digraph on $n \ge n_0$ vertices. Suppose that $\delta^0(G) \ge \eta n$ and G is a robust (ν, τ) -outexpander. Let C be any oriented cycle on n vertices and fix $x_C \in V(C)$. Given any $v_G \in V(G)$, there is a copy of C in G in which x_C is embedded onto v_G .

Note that the proof of Theorem 3.4 in [20] immediately yields Theorem 5.4. Indeed, in this proof, when embedding an *n*-vertex oriented cycle C, segments Q_i of the cycle are embedded greedily (see Step 4 in the proof of Theorem 3.4 in [20, Theorem 49]). Thus, we may line things up so that one of the Q_i contains x_C (roughly in the middle of Q_i). We then (via Lemma 5.1) greedily construct a copy of Q_i in G that embeds x_C onto v_G .

We now explain how Theorem 5.4 implies Theorem 5.3.

Proof of Theorem 5.3. Let G and P be as in the statement of the theorem. Write $P = v_1 \dots v_n$. We will define an auxiliary digraph G^* whose precise construction depends on the orientations of the edges incident to v_1 and v_n in P. For instance, suppose that $|N_P^+(v_1)| = |N_P^+(v_n)| = 1$ (and $|N_P^-(v_1)| = |N_P^-(v_n)| = 0$); the other cases can be handled analogously. Construct the digraph G^* from G by deleting x and y and adding a vertex v_{xy} so that (i) $N_{G^*}^-(v_{xy}) := N_G^+(x) \setminus \{y\}$ and (ii) $N_{G^*}^+(v_{xy}) := N_G^+(y) \setminus \{x\}$. Note that G^* is a robust $(\nu/2, 2\tau)$ -outexpander with $\delta^0(G^*) \geq \eta |G'|/2$.

Let C be the oriented cycle obtained from P by deleting its startpoint v_1 and its endpoint v_n , and adding a new vertex $v_{1,n}$ that receives an edge from v_2 and sends out an edge to v_{n-1} . By Theorem 5.4 there is a copy of C in G^* in which $v_{1,n}$ is embedded onto v_{xy} . The definition of $N^+_{G^*}(v_{xy})$ and $N^-_{G^*}(v_{xy})$ now ensures that this copy of C corresponds to a copy of P in G that starts at x and ends at y, as desired.

With the above results at hand, we can now easily prove Theorem 3.5.

Proof of Theorem 3.5. Define additional constants so that

 $0 < 1/n_0 \ll \nu' \ll \varepsilon \ll \beta \ll \nu \ll \tau \ll \tau' \ll \eta.$

Let $n \ge n_0$ and let $G, Q_1, \ldots, Q_k, u_1, \ldots, u_k, v_1, \ldots, v_k$ be as defined in the statement of the theorem.

Since $\beta \ll \nu$, certainly $|Q_i| \ge 1/\beta \ge \lceil 2/\nu^3 \rceil$. In particular, we can repeatedly apply Lemma 5.1 to obtain the required copy P_i of Q_i for each path Q_i with $|Q_i| \le \varepsilon^{1/4} n$. (Formally, whenever constructing such a P_i , one should first delete all the other oriented paths P_j constructed before, as well as all of $u_1, \ldots, u_k, v_1, \ldots, v_k$ other than u_i and v_i , and then apply Lemma 5.1 to the resulting subgraph of G. This ensures all the oriented paths P_j are disjoint.)

For each oriented path P_i already constructed, delete its vertices from G; let G' be the resulting induced subgraph of G. Note that at most $\frac{1}{\beta^2} \cdot \varepsilon^{1/4} n \leq \varepsilon^{1/5} n$ vertices of G have been deleted. Thus, G' is a robust $(\nu/2, 2\tau)$ -outexpander with $\delta^0(G) \geq \eta |G'|/2$. By relabeling if necessary, we may assume that we still need to construct the copies of Q_1, \ldots, Q_t in G for some $t \leq 1/\beta^2$, and now $|Q_i| \geq \varepsilon^{1/4} n$ for all $i \in [t]$.

Set $W_0 := \{u_1, \ldots, u_t, v_1, \ldots, v_t\}$; so certainly, $m_0 := |W_0| \le \varepsilon^{1/4} |G'|$. For each $i \in [t]$, define $m_i := |Q_i| - 2 \ge \varepsilon^{1/4} n - 2 \ge \varepsilon^{1/3} |G'|$. Thus, we can apply Lemma 5.2 to obtain a partition $\{W_0, W_1, \ldots, W_t\}$ of V(G') such that for all $i \in [t]$:

- $|W_i| = m_i$ and $G'[W_i]$ is a robust (ν', τ') -outexpander;
- $d^+_{G'}(x, W_i), d^-_{G'}(x, W_i) \ge \eta m_i/8$ for every $x \in V(G')$.

Next add u_i, v_i to W_i for each $i \in [t]$. We now have that $G'[W_i]$ is a robust $(\nu'/2, 2\tau')$ outexpander with $\delta^0(G'[W_i]) \geq \eta |W_i|/10$ (for each $i \in [t]$). Finally, Theorem 5.3 implies
that in each $G'[W_i]$ we have the desired copy P_i of Q_i that starts at u_i and ends at v_i . This
completes the proof.

5.2. **Proof of Theorem 1.6.** In this subsection we prove Theorem 1.6. For this, we will use the following strengthening of Lemma 5.1.

Lemma 5.5. Let $0 < 1/n_0 \ll \nu \ll \tau \ll \eta \ll 1$. Let $n \ge n_0$ and let $\lceil 2/\nu^3 \rceil < k \le n$. If G is an n-vertex digraph with $\delta^0(G) \ge \eta n$ such that G is a robust (ν, τ) -outexpander, then for all distinct $x, y \in V(G)$ and all oriented paths P on k vertices, there is a copy of P in G that starts at x and ends at y.

Proof. Define additional constants so that

$$0 < 1/n_0 \ll \nu' \ll \varepsilon \ll \nu \ll \tau \ll \tau' \ll \eta.$$

Let $n \ge n_0$ and define G, P, x, y as in the statement of the lemma.

If $\lceil 2/\nu^3 \rceil < |P| \le \nu^3 n/4$, then we are immediately done by Lemma 5.1. So suppose that $|P| > \nu^3 n/4$.

If $\nu^3 n/4 < |P| < (1 - \varepsilon^{1/3})n$, set $W_0 := \{x, y\}$; $m_0 := |W_0| = 2$; $m_1 := |P| - 2 \ge \varepsilon^{1/3}n$; $m_2 := n - |P| \ge \varepsilon^{1/3}n$. Now we apply Lemma 5.2 to obtain sets $W_1, W_2 \subseteq V(G)$. Add x and y to W_1 ; we have that $G[W_1]$ is a robust $(\nu'/2, 2\tau')$ -outexpander with $\delta^0(G[W_1]) \ge \eta |W_1|/5$. Note that $|W_1| = |P|$. Theorem 5.3 now implies that $G[W_1]$ contains a copy of P that starts at x and ends at y. Finally, if $|P| \ge (1 - \varepsilon^{1/3})n$, consider any induced subgraph G' of G on |P| vertices that contains x and y. Then G' is a robust $(\nu/2, 2\tau)$ -outexpander with $\delta^0(G') \ge \eta |G'|/2$. Theorem 5.3 implies that G' contains a copy of P that starts at x and ends at y, as desired.

We are now ready to prove Theorem 1.6.

Proof of Theorem 1.6. Define additional constants so that

$$0 < 1/n_0 \ll \nu \ll \tau \ll \alpha \ll \zeta \ll \gamma, 1/k.$$

Let $n \ge n_0$ and let G be an n-vertex digraph as in the statement of the theorem. Let C be an oriented cycle on at most n vertices that is not a directed cycle of length more than $\lfloor n/k \rfloor$. We will prove that G contains C. We split into three cases.

Case 1: $|C| \leq 1/\nu^4$. Consider the (undirected) graph G^* on vertex set V(G) where x and y are adjacent in G^* precisely if both xy and yx are edges in G. Note that $\delta(G^*) \geq \gamma n$. Thus, e.g., the Kővári–Sós–Turán theorem implies that G^* contains every even length cycle of order up to $1/\nu^4$. Hence, G contains every oriented cycle of even length up to $1/\nu^4$.

We are therefore done unless |C| is odd. However, in this case our argument above implies that G contains a copy C' of the 'double edge' cycle on |C| - 1 vertices. Let x and y be two neighboring vertices along C'. As $\delta(G) \ge (1 + \gamma)n$, either $d_G^+(x) + d_G^-(y) \ge (1 + \gamma)n$ or $d_G^-(x) + d_G^+(y) \ge (1 + \gamma)n$. Without loss of generality we may assume the former holds. So there is some $z \in N_G^+(x) \cap N_G^-(y) \cap (V(G) \setminus V(C'))$. Since every oriented cycle of odd order contains a vertex of in- and outdegree 1, adding z to C' immediately yields a copy of C, as desired.

Case 2: $1/\nu^4 < |C| \leq \lceil n/k \rceil$. In this case we apply Proposition 2.1 to obtain a partition $\{V_1, \ldots, V_t\}$ of V(G) into at most k classes. In particular, for one of these classes V_i we have that:

- $|V_i| \ge \lceil n/k \rceil;$
- $G[V_i]$ is a robust (ν, τ) -outexpander with $\delta(G[V_i]) \ge (1 + \frac{1}{k+1} + \frac{\zeta}{2})|V_i|$.

Lemma 5.5 implies that $G[V_i]$ contains a copy of C, as desired.

Case 3: $|C| > \lceil n/k \rceil$ and C is not a directed cycle. Randomly select a subset X of V(G) of size |C|. Chernoff's bound for the hypergeometric distribution implies that, with high probability, $\delta(G[X]) \ge (1 + \gamma/2)|X|$. Theorem 1.3 implies that G[X] contains a copy of C.

We now prove the moreover part of the theorem. Given $n \ge 2$, consider an *n*-vertex digraph G with $\delta(G) \ge \lfloor \frac{3n}{2} \rfloor - 1$. As before, let G^* be the (undirected) graph on V(G) where x and y are adjacent in G^* precisely if both xy and yx are edges in G. Note that $\delta(G^*) \ge \lfloor \frac{n}{2} \rfloor$ and thus [1, Theorem 2.3] implies that (a) G^* is pancyclic (i.e., contains a cycle of every possible length) or (b) G^* satisfies one of the following conditions:

- (i) G^* is the union of two complete graphs $K_{(n+1)/2}$ that share a single vertex;
- (ii) there is a partition A, B of V(G) such that |A| = (n+1)/2, A is an independent set in G^* and there are all possible edges between A and B in G^* ;

- (iii) G^* is a copy of the complete bipartite graph with n/2 vertices in each of its vertex classes A and B;
- (iv) G^* is a copy of the cycle C_5 on 5 vertices.

If (a) holds then clearly G contains every oriented cycle of every possible length. If (ii) or (iii) hold then as $\delta(G) \geq \lfloor \frac{3n}{2} \rfloor - 1$, there is an edge in G[A]; this edge, together with the structure obtained from G^* , ensures G contains every oriented cycle of every possible length. Similarly, if (i) or (iv) hold then there is an edge present in G that is not a double edge. One can then easily use this edge with the structure from G^* to show that G contains every oriented cycle of every possible length. \Box
